31. **Faradic Current in Aphonia.**—A study of two cases of aphonia has led Hernaman-Johnson to form conclusions regarding the pathology and treatment of persistent post-catarrhal aphonia. The larynx is primarily a mechanical device for the production of vocal sounds, and depends for its proper functioning even more on the integrity of its muscles and nerves than on the healthiness of their covering. In chronic catarrh of this organ, the muscles become secondarily affected, and the delicate terminals of the motor nerves in all probability undergo an inflammatory degeneration. An acutely inflamed mucosa doubtless demands local sedative applications; and even when the trouble has become chronic, astringent sprays, paintings, etc., can often play an important part. But the tendency in many chronic cases is for the mucous engorgement to disappear to a great extent, whereas the damage to the neuromuscular apparatus remains. Under such circumstances it is unreasonable to expect a cure by the ordinary means. On the other hand, improvement may be looked for from such measures of "natural therapy" as produce benefit in similar pathologic conditions elsewhere, e. g., in the form of facial palsy which is the result of exposure to the cold. Hernaman-Johnson says that in treating paresis of laryngeal muscles by faradization, the secret of success lies in the regular and persistent use of mild currents, which are not calculated to produce violent contractions of opposing healthy muscles. If carefully applied for a prolonged period this form of electricity exercises a selective action on the affected structures and eventually restores their tone. Remarkable as are the results in suitable cases, however, it must not be regarded as a panacea for each and every form of catarrhal aphonia. When the laryngoscope shows marked swelling and congestion of the cords, the mucous membrane must be attacked vigorously on orthodox lines. Nevertheless, even when the mucosa is the part most at fault, the judicious use of the interrupted current, he declares, forms a valuable adjunct to routine treatment.

32. **Phlegmasia Alba Dolens.**—Five days after delivery, Curtis's patient developed phlegmasia alba dolens in the left leg. Under treatment she progressed favorably for seven days when she was seized with violent pains in the left chest and shortness of breath. The respirations were 72; pulse, 108, regular, but very feeble; the temperature, 100 F. The extremities were cold. She complained of intense pain over the epigastrium, precordia, and lower axilla. An impaired note was found over the lower part of the axilla, and the breath sounds over this area were badly transmitted; no friction sound was heard. A soft systolic murmur could be heard over the pulmonary area and the second sound was accentuated. She suffered from retching and some vomiting, and the smallest amounts of liquid nourishment caused great pain over the precordia and lower axilla. As the stomach was dilated this was attributed to pressure on the diaphragm, interfering with cardiac and respiratory movements. Hot water bottles were applied to the feet and hot applications to the chest. She was given iced milk and soda-water with brandy in small quantities at frequent intervals. She was also given the following mixture every four hours:

℞		gm. or c.c.	
Bismuth carbonate	gr. x		65
Aromatic spirits of ammonia...............	m. xv	1	
Compound tincture of cardamoms...........	m. x		60
Mucilage, q. s., and water................	℥i	30	

On the following day the vomiting had ceased. The respirations were 66; pulse, 102, and temperature, 101 F. She still had considerable pain over the lower axilla, and a marked friction sound could be heard over this area. It was noticed that the swelling in the left leg had diminished considerably; it was much softer and free from pain. The pulmonary systolic murmur could still be heard, although it was not so marked. Three days later there was a considerably impaired note over the lower half of the upper lobe, and the whole of the lower lobe and axilla, with marked tubular breathing, bronchophony and pectoriloquy. The temperature was 99 F., respiratory rate 60, and pulse 96, regular, and of medium tension. The pulmonary sounds were clear. There was good air entry at the base, but dulness persisted over the axilla, the lower half of the upper lobe, and the upper half of the lower lobe; and over these areas there were still tubular breathing, bronchophony and pectoriloquy. There was still an occasional dry cough but no expectoration. The temperature was normal. The left leg had resumed its normal size. The lung symptoms gradually cleared up.

33. **Influence of Quinin on Phagocytosis.**—Smith made a series of researches to ascertain, if possible, the truth of the statement that quinin, like alcohol in excess, inhibits phagocytosis, and is therefore contraindicated in septic conditions. The opsonic index was taken as a basis for the work, with the additional factor of a solution of quinin and morphia. The very soluble acid hydrochlorid of quinin was selected because it is much less irritating than the sulphate and contains 8 per cent. more quinin. Morphin hydrochlorid, 1/8 grain, was added to each 10 grains of the quinin salt. It was roughly calculated that a 10-grain dose given to a person weighing 140 pounds, if entirely absorbed, would represent in the blood a proportion of 1 to 7,500. The influence of this solution (1 to 7,500, equivalent to a 10-grain dose) on the phagocytosis of different kinds of pathogenic organisms (e. g., streptococci, staphylococci, pneumococci, *B. coli, B. influenzæ, B. pseudodiphtheriæ*, and *B. tuberculosis*) was contrasted with stronger and weaker solutions to ascertain the effect of varying doses. In the majority of the eleven sets of experiments, there was an increased phagocytosis, always most marked with the 10-grain dose solution. Instead of inhibiting phagocytosis, the addition of quinin and morphia, in what may be considered the "ideal" dose, greatly increased it. Smaller doses in all the groups were less effective, and one important fact was clearly demonstrated—namely, that very large doses (30 and 40 grains), instead of increasing, actually diminished phagocytosis, sometimes to the extent of 50 per cent.

41 *Non-Cystic Ovarian Tumors. M. Mériel.
42 *Stenosis of the Pylorus from Muscular Hypertrophy. P. Fredet and L. Guillemot.
43 *Megacolon. M. Patel.

41. **Non-Cystic Ovarian Tumors.**—Mériel discusses all kinds of ovarian tumors outside of cysts. He has found only seventeen fatalities in the 289 operative cases on record since 1900, the mortality thus being from 4 to 4.5 per cent. The percentage of permanent cures has been 15 per cent. in the 372 cases compiled by Estor between 1881 and 1900 and the proportion is much higher in later series. The figures show that the operative mortality is no higher when both ovaries and the uterus are removed. The final outcome, he states, is much better for these non-cystic ovarian tumors, especially the malignant, than with cancer of other genital organs or organs elsewhere. This favorable prognosis includes both the operative and remote results, and it encourages early operation in case of a solid, movable tumor of the ovary. As there is no reliable sign to differentiate the benign from the malignant tumors, there should be no delay; the abdomen once opened the surgeon can then decide whether to continue or abandon the operation. Bilateral ovariotomy can be done without interrupting a pregnancy; after delivery the ovarian tumor should be removed without delaying for more than two or three days. The favorable figures shown by the latest statistics permit more initiative than in the past. Metzger has compiled 150 cases of ovarian cancer complicating gastric cancer, and Hartmann has reported a case in which he successfully removed a cancer in both ovaries and the primary cancer in the pylorus, the patient, a woman of 38, leaving the hospital in good condition; the operations were done in two sittings with a month's interval. In Boeckel's case two large cancers were removed from the ovaries; necropsy a few months later disclosed an unsuspected cancer in the stomach.

42. **Stenosis of the Pylorus in Infants from Muscular Hypertrophy.**—Fredet and Guillemot do not consider the anatomic lesion as necessarily entailing fatal impermeability; the superposed factors are the dangerous elements—the inflammatory swelling of the mucosa and spasm of the hypertrophied muscle which aggravate the stenosis. These latter factors may be influenced by medical treatment, resting the stomach by feeding a teaspoonful at a time, merely iced boiled water at first, and combating the spasm by lavage, hydrotherapy and local heat. The dietetic measures are the most important; the stomach will sometimes tolerate up to 5 gm. of breast milk at a time. These small amounts should be kept up for about two weeks and then the amount gradually increased. The food with which he has been most successful is a milk gruel or malt soup. Sedatives are given to reduce the tendency to spasm. In the severe forms lavage may be useful but it sometimes aggravates the weakness; in one case it seemed to be responsible for the collapse observed. In case operative treatment becomes necessary, partial pylorotomy by a straight longitudinal incision down to the mucosa, enables the muscular fibers to spread. The lips of the longitudinal incision are then drawn apart and sutured together again to form a transverse line. The two children on whom this technic has been applied recovered at once and are now healthy and well developed. Weber has reported two similar cases. In 185 operations for this form of stenosis the immediate mortality was 47 per cent., but the mortality was only 26.31 per cent. in the thirty-eight cases in the last three years in which the operation was this partial pylorotomy. Fredet and Guillemot warn especially against letting the child become chilled during the operation. The outcome is immediately favorable in the children without existing gastro-enteritis, but when this is present convalescence is a little retarded but not so much as might be expected. Only two of the fifty-three children operated on according to this preferred technic of posterior gastro-enterostomy succumbed later to progressive debility.

43. **Megacolon.**—Patel gives a historical sketch of idiopathic dilatation of the large intestine or Hirschsprung's disease, and reviews 223 cases with an operation or necropsy; all but seventy-three were in children. About 57 per cent. of the seventy-four children operated on and 57 per cent. of the forty-one adults were cured by the operation. His review shows that the mortality grows less as the children increase in years; under the age of 2 there were thirteen deaths for thirteen operations, some merely an exploratory laparotomy; from 2 to 5, only four of the fourteen children survived, but between the ages of 5 and 15 there were twenty-seven recoveries to ten deaths and between 15 and 50 years of age there were twenty-two recoveries to eight deaths; after the age of 50 only one recovery is reported to ten deaths. He thinks that it is not enough to fasten or take up a fold in the colon, while resection is too serious; unilateral exclusion gives the best results from all points of view.

Bulletin de l'Académie de Médecine, Paris

44 *Paralysis of the Recurrent Laryngeal Nerve and Mitral Stenosis. E. Boinet.

44. **Paralysis of the Recurrent Laryngeal Nerve and Mitral Stenosis.**—Boinet reports two cases and discusses what has been published on this subject by Osler and others, all proving *that recurrent paralysis is liable to accompany mitral stenosis*, either from direct compression of the left recurrent nerve by the left auricle or by traction downward from the dilated and hypertrophied right ventricle or from both these factors. This cause for the paralysis should be borne in mind after exclusion of the usual causes.

45 *Spinal Anesthesia in Gynecology. (Etude sur la rachistovainisation.) Violet and Fisher.
46 Operative Treatment in Cholelithiasis. (Du choix de l'intervention dans la lithiase biliaire.) G. Cotte.
47 Traumatic Dislocation of the Scaphoid Bone in the Foot. E. Destot.

45. **Spinal Anesthesia.**—Violet and Fisher have compiled 30,000 cases from the literature to which they add 270 cases from Pollosson's gynecologic clinic, and discuss the special indications, technic and results. They regard raising the pelvis as decidedly dangerous at first, while the drug is diffusing, and this phase may last for twenty or thirty minutes. The great danger of the spinal technic is the liability to stoppage of the respiration; this occurred twice in their 270 cases, but they were able to revive one of the patients. In the fatal case necropsy disclosed an unsuspected pleural effusion which should have contraindicated general anesthesia, especially by the spinal technic. Another fatality was evidently the direct result of lowering the patient's head too soon after the injection; some of the fluid had been lost in making the injection and the pelvis was raised at once. The skin was incised seven minutes after the injection and the patient, an obese woman with cancer of the cervix uteri, stopped breathing and could not be revived. They list further the details of thirty-six other fatalities in European literature following injection of stovain, tropacocain, or novocain for spinal anesthesia. In twenty cases the fatal syncope occurred within fifteen minutes and in others not until after several hours. In four of the cases suppurative meningitis was evidently due to lack of asepsis in the technic. In four other cases mechanical interference with the action of the lungs from an effusion was responsible for the fatality; in fourteen cases the cachexia or infection was already in a dangerously advanced stage. In seven of the total thirty-six fatalities the stovain must be directly incriminated, they think. Paralysis of legs or sphincters developed in sixteen cases, generally subsiding after a few days or months, but entailing fatal complications in bladder or kidney in two cases and fatal infection from an eschar in a third, while in three cases the paralysis or ataxia seems to be permanent. Study of these cases shows a pre-existing predisposition—syphilis or alcoholism—which should have contraindicated the method or else the dosage was too large or asepsis violated. The spinal method, the authors state, is particularly adapted for gynecologic operations, as the field is all in one plane innervated from the same segment of the spine, the relaxation of the muscles is complete, there is no vomiting, the operative shock is less than with other technics and there is no irritating action from the anesthetic on the lungs;

the patients can be fed earlier and convalescence is shortened But the technic requires skill and the method has its indications and contraindications Among the latter are strangulated hernia, dating from several days, septicemia and tuberculosis—in several cases the spinal injection seemed to localize the trouble in the meninges, dyspnea of mechanical origin pregnancy arteriosclerosis, syphilis, tabes or any history of a cerebrospinal affection

Semaine Médicale, Paris

49 **Progress in the Campaign Against Tuberculosis**—Frankel states that the statistics for Prussia show that the total deaths from tuberculosis in 1909 were 9 11 per cent of the total mortality, against 9 13 per cent in 1908 There has been a constant decline since 1875, when the deaths from tuberculosis totaled 88 283, against 60,871 in 1909, while the population in this period has increased from 28,000,000 to 39,000,000 The number of tuberculous individuals receiving institutional treatment has increased during this period from less than 12 000 to over 102,000, but the institutions for the advanced cases are still shunned as of yore Of the 42,232 tuberculous insured given a course of sanatorium treatment 35 131, that is 83 per cent, regained their earning capacity This regaining of earning capacity persisting for five years and over is recorded for 27 per cent in 1897, and this percentage has increased constantly up to 46 per cent in 1905 Besides the three stages of the Turban classification, the statistics now embrace a stage O, this represents "a more favorable condition than stage I"

50 **Diseased Adnexa**—Landau reviews the changes and progress realized in the treatment of chronic inflammation or suppuration in the uterine adnexa, and cites his own experience His figures seem to sustain his views in regard to the advantages of abdominal operating for uncomplicated affections of the adnexa, unilateral or bilateral, while the radical vaginal route is reserved for the cases with complications, preferably the abdominovaginal technic The mortality in his 780 abdominal operations was 2 per cent , by the vaginal route alone, the mortality was 4 2 per cent. in 543 cases of chronic suppuration or inflammation since 1893, while it was 7 6 per cent in ninety two cases with complicating pelvic abscess Prophylaxis of adnexitis includes *prevention or early cure* of gonorrhea and of sepsis after abortion and childbirth, and efforts to ensure asepsis in minor gynecologic measures, curetting, etc

53 **Apparent or Actual Azoospermia**—Furbringer warns physicians *not to be too hasty in concluding* as to the existence of azoospermia, a second examination may give opposite findings from the first He has encountered about a thousand cases of actual azoospermia and also numerous cases in which he had to reverse the first diagnosis The lack of motility is the essential element for the diagnosis The movements of the spermatozoa may be impeded by coagulation of the medium but they regain their motility, if normal, as the medium is liquefied by heat or otherwise Hot weather and extreme cold may also affect the motility of normal spermatozoa, as may also the presence of an antiseptic or indifferent powder. In many cases of assumed sterility in the husband some gynecologic trouble in the wife was finally discovered, notwithstanding the assurance of the gynecologists to the contrary at first

54 **Mishaps and Hypersusceptibility with Serotherapy**—Jochmann has had only two cases of threatening collapse in his extensive experience with serotherapy in various diseases, these were both after intravenous injection of large amounts of antistreptococcus serum in scarlet fever An existing heart disease in one case showed signs of aggravation after an intravenous injection of 50 c c of antistreptococcus serum, and he now regards heart disease as contraindicating the intravenous route He urges the production of more concentrated serums, as the untoward effects are observed with the larger doses, and further pleads that other animals besides horses should be utilized in making the serums—mules, goats, asses and cows—so that by interchanging the serums in cases requiring repetition of the doses it may be possible to avoid all danger of hypersusceptibility Netter has reported that manifestations of serum sickness have been reduced from 20 to 3 or 4 per cent in his experience with 600 cases since he has made it a routine practice to inject or give by the mouth from 0 75 to 1 gm (from 12 to 15 grains) of calcium chlorid for three days in succession

57 **Ehrlich's "606"**—Lesser here states that this preparation exerts the same action as arsenic in other forms in other diseases as well as in syphilis, only in a much simpler, speedier and more energetic manner The general condition improves, the patients regain appetite and their pallor yields to the tint of comparative health This organotropic effect, as he calls it, is also the main factor, in his opinion, in its efficacy in syphilis, as it reinforces the natural defensive processes He doubts whether the direct destructive action of the new remedy on the spirochetes in the body is the principal factor in the cure of syphilis The dosage should be selected with the aim to influence the natural defensive processes and increase the vitality of the cells without reference to any direct destructive action on the spirochetes It has been his impression from his observation that the symptoms and the transformation of the Wassermann reaction are not influenced any more by large than by moderate doses If the reaction is still positive six or eight weeks after the first injection it might be advisable to repeat the dose A negative reaction seems to indicate, he thinks, at least a temporary inactivity on the part of the spirochetes

63 *Typhoid Suppuration in the Kidneys (Die suppurativen Nierenkomplikationen des Typhus abdominalis mit bes Berucksichtigung ihrer chirurgischen Bedeutung) E Melchior Commenced in No 18

61 **Non-Operative Treatment of Cancer.**—Venus lists 367 articles on the treatment of cancer with serotherapy, anes

thetics or suction. It is possible that a specific serum may yet be produced, but the results to date, he says, have been disappointing. The best results have been obtained with the epithelium serum, based on cytotoxic action, and further research is indicated in this line. Serotherapy with streptococcus or mixed cultures has proved ineffectual, although in inoperable sarcoma or after operation, Coley's fluid might be given a trial. No benefit seems to have been obtained with injection of local anesthetics, which Spiess and Schleich have tried. Ritter has applied suction hyperemia, but his silence since his last favorable announcement, three years ago, does not speak very favorably for the method.

63. **Typhoid Suppuration of the Kidney.**—Melchior has compiled fifty-six reports or discussions of suppurative complications on the part of the kidneys with typhoid, with special regard to their surgical treatment, discussing in turn abscesses, pyelonephritis, pyonephrosis and abscess formation in the tissues around the kidney, as well as typhoid infection of hydronephrosis and of a kidney containing concrements. Among the numerous cases described are some which show the possibility of long latency before serious local symptoms develop, ten years in Meyer's and six years in Greaves' case. In both, however, careful examination would probably have revealed the suppuration long before, while with typhoid bone abscess the interval may be absolutely free from symptoms. Post-typhoid pyuria should always be regarded as a serious symptom, and the source for the pus should be determined so that proper treatment can be applied at once. Typhoid suppuration seems to be rather benign in nature; in Greaves' case the typhoid pyonephrosis healed under mere drainage without a fistula. Nephrectomy should be considered with pyonephrosis destroying the organ, and also with destruction from suppuration with kidney stone. The patients with these post-typhoid complications are generally chronic bacilli-carriers.

68. **Functional Tests of the Pancreas.**—Hirschberg reports the details of six cases in which the combination of the various functional tests of the pancreas gave instructive findings. They are more reliable in the chronic cases. In acute pancreatitis, Wohlgemuth's method of determining the diastase in the urine, he states, is a valuable aid in diagnosis. It was described in THE JOURNAL, March 5, 1910, page 825.

71. **Creeping Exercises and Orthostatic Albuminuria.**—Pechowitsch says that the experiences at Bier's clinic with Klapp's creeping exercises have confirmed the fact that orthostatic albuminuria is the result of an exaggerated lordosis of the lumbar spine, mechanically obstructing the venous outflow from the kidneys. The creeping exercises improve conditions in the circulation by their favorable action on the general health as well as on the local condition.

82 Disputed Cases in Regard to Workmen's Compensation, Etc. (Die wichtigeren Entscheidungen des Reichs-Versicherungs-Amts aus den Jahren, 1905-1909.) E. Franck.

75. **Abdominal Contusions.**—Föderl concludes his long study of this subject by warning that any contusion of the abdomen is liable to induce symptoms of shock. It is impossible to determine the extent of the internal injury from the presence or the intensity of the shock or the total absence of signs of shock. He has had patients with severe laceration of the liver or rupture of the bowel who were able to repair to the hospital on foot. Subnormal temperature may be due to the shock and anemia; fever soon after the trauma shows an inflammatory process. The pulse and heart action are not influenced by internal injury except in case of anemia or peritonitis. Nausea and vomiting do not necessarily accompany anatomic injury. With extensive hemorrhage or peritonitis, the decision to operate generally comes too late; the operation is designed to forestall these. Sedatives mask the clinical picture and obscure the diagnosis and indications for treatment. Lack of active initiative on the part of the general practitioner is particularly serious in cases of abdominal contusions. These patients require specialist oversight at the earliest possible moment.

76. **Physical Examination Before and After Sanatorium Treatment of Tuberculosis.**—Rumpf's article was read before the last annual meeting of German sanatorium physicians; he emphasizes the importance of the physical findings and the sources of error. The findings are more instructive, he says, if the patient breathes through the mouth. He discusses in detail the question as to whether the changes in the lungs are due to tuberculous infection or not. It is a great gain when the râles can be completely banished during the course of treatment and no crepitation is heard even after coughing. The infectious process is much more liable to spread from a focus with liquefaction. He found 79 per cent. of the patients with full earning capacity after several years of those patients who lost their râles entirely during treatment; 1.5 per cent. had died. Among those in whom the râles were not entirely abolished, only 31 per cent. were found with full earning capacity, and 42 per cent. had died. The importance of distinguishing between the various types of râles is shown by the late findings in his cases: full earning capacity in 74 per cent., and 4 per cent. had died of those patients with nonsonorous râles, while only 22 per cent. had full earning capacity, and 57 per cent. had died of those with tinkling râles. The latter always indicate destruction of tissue; it is not necessary to wait for the pronounced metallic tinkling râles to reveal tissue destruction. His experience has demonstrated that the length of time required to banish the râles varies widely in different patients. The aim should be to prolong the sanatorium treatment until this is realized for as large a proportion of patients as possible.

78. **Connection Between Syphilis and Pernicious Anemia.**—In Roth's case, the young woman made rapid progress under mercurial treatment and the blood findings returned to normal in the course of three or four months, although the Wassermann reaction was still positive.

79. **Organotherapy and Postoperative Tetany.**—Bircher writes from Aarau that he has operated in 1,400 cases of goiter during the last sixteen years without postoperative tetany in any instance, but lately two cases developed in the course of a month, one in a woman of 55 and the other in a girl of 18. In both cases the tetany was evidently due to loss of parathyroid substance, and the tendency to tetany was promptly cured by parathyroid treatment. This experience, he asserts, shows the possibility of curing tetany by this simple means. It also demonstrates that it is not always possible to refrain from removing the parathyroids in operating on the thyroid. Thyroid treatment has never given any results in this form of postoperative tetany; in the two cases reported it was given first and without effect. This rendered more striking in both the cases the prompt efficacy of the parathyroid treatment. It is possible that the remaining parathyroids might

have developed a compensating hypertrophy in time, but in the meanwhile there was danger of the patients succumbing to the severe manifestations.

83. **Contracted Pelvis.**—It has been v. Herff's experience at Basel that conservative measures give as good if not better ultimate results than have been reported from any clinic with the recently introduced operative technics in management of delivery with contracted pelvis. In the 10,289 births in the last seven years contracted pelvis was encountered in 13.8 per cent.; the maternal mortality was 0.4 per cent. and the mortality of the children 7.3 per cent. The main reliance is on artificial premature delivery which was completed spontaneously in 86 per cent.; there was no mortality for which the management of the birth could be incriminated. Operative treatment exposes the mother to grave danger at the time and possibility of later impairment of her working capacity. He argues that the survival and health of the mother of the family far outweigh the consideration for the life of the infant in cases of contracted pelvis, as a rule. The aim should be to reduce infant mortality during the first year or two of life rather than to sacrifice the mothers to bring a few more infants into the world by Cesarean section or pubiotomy. Comparison of his figures with those of Döderlein's clinic, where operative measures are more frequently applied, shows that the final outcome is much better. No permanent injury resulted for the mother from high forceps in his experience, while with pubiotomy from 32 to 50 per cent. of the women have been left with permanent injury according to the reports published by four leading obstetricians (Schläfle, Zweifel, Bumm and Leopold).

84. **Instrumental Artificial Respiration.**—Läwen and Sievers report a case in which the symptoms indicated a brain tumor and respiration suddenly ceased completely. The respiration was kept up by the usual maneuvers for an hour, the pulse being still full. The patient was entirely unconscious, the pupils were dilated and the reflexes were abolished. An opening was then made into the trachea, a cannula introduced and connected with an apparatus which pumped air regularly into the lungs for nine hours, keeping up the heart action while the blood-pressure ranged from 40 to 95 mm. mercury. Necropsy revealed internal hydrocephalus and hemorrhage into the ventricle shutting off all the cerebral functioning and flattening the medulla oblongata. Notwithstanding this serious condition, the instrumental artificial respiration kept the heart beating for nine hours. The great drawback to the method is the necessity for tracheotomy. An illustrated description is given of the apparatus used here for the first time on man, although it had long proved its usefulness for animals.

THE USE OF TYPHOID VACCINES IN TYPHOID FEVER*

JAMES M. ANDERS, M.D., LL.D.
Professor of Medicine and Clinical Medicine in the Medico-Chirurgical College
PHILADELPHIA

The vaccine treatment of typhoid fever has been tested in recent years by a number of clinicians with varying results. Fraenkel[1] was the first to call attention to the subject of the treatment of this disease by vaccine therapy. Since the commencement of the year 1909, a considerable number of other writers have reported individual experiences of the use of typhoid vaccines as a means of cure. While the medical profession is not, in any marked degree, enthusiastic in regard to the question, every new remedy or method of treatment that rests on a reasonably secure, scientific basis deserves an extended trial before it is rejected. Certain fundamental principles and facts, which are generally accepted by laboratory experts, should be understood also by the clinician who intends to use vaccines in the treatment of typhoid fever and other diseases. Among these are:

1. The object of vaccine therapy is to induce an active immunity by introducing an added amount of morbific material, so that "by manufacturing an increased amount of the protective bodies, it (the body of the vaccinated person) shall inhibit the growth of the invading organisms, and cut short the disease."[2]

2. When the *Bacillus typhosus* undergoes solution in the human organism, endotoxin, to which its pathogenic action is wholly attributable, is set free.

3. In the process of immunization, both bacteriolysis and phagocytosis play a part. Emery[3] rightly holds that phagocytosis is of chief importance from the fact that typhoid bacilli liberate their endotoxin when dissolved by means of bacteriolytic serums.

4. In serious types in which the system is already overwhelmed with the typhoid bacillus and its toxins, it is unwise to employ the vaccine treatment, for it may be a source of fresh danger. Under these circumstances, there can be no response to attempts at stimulating the production of immunizing substances by the introduction into the system of more of the specific poison. On the contrary, there must occur an aggravation of the symptoms.

5. When typhoid fever is being treated with vaccines the determination of the opsonic index in routine private practice is too time-consuming a procedure to be adopted, although desirable, when it can be carried out, in hospital work. Fortunately, it is generally conceded to be unnecessary to estimate the opsonic index, if the effect of the treatment on the general clinical symptoms be closely observed.

6. Typhoid fever is an acute bacteriemia plus toxemia, often fulminating in character, and not a localized infection; hence, brilliant results from the vaccine treatment for the cure of this disease are scarcely to be expected.

It may be questioned seriously whether, on account of the foregoing facts, it is not injudicious to practice vaccine therapy in the severer and so-called malignant types of typhoid fever. In this connection, it should be recollected that chronic infections in which the specific organism is, more or less, completely walled off from the general circulation, with slow absorption of toxins into the blood are those in which the vaccine therapy gives its best results. Here, the production of antibodies can be stimulated "by the introduction of dead bacilli into the general circulation, and these can effectually exercise their therapeutic properties on the bacteria in a chronic lesion" (Swan).

A considerable number of clinical observers have been impressed with the curative or controlling influence of proper inoculations with appropriate bacterial vaccines in typhoid fever. One of the earliest observers, Captain Smallman,[4] employed the method in thirty-six cases with three deaths or a percentage of 8.3. He remarks especially on the absence of prolonged cases, of complications, of sequelæ and of relapses; and, further, that a local infection during convalescence, for example, periostitis of the tibia, can be dissipated by the local injection of vaccines. From an observation of forty cases, Watters and Eaton[5] suggest that the early administration of typhoid vaccine appears to shorten, in many cases, the duration of the disease and to cause the affection to run a mild course. Semple[6] treated nine cases, six of which showed well-marked improvement after the inoculations, especially two cases treated with autogenous vaccines. In the remaining three, amelioration of the symptoms occurred.

On the other hand, certain writers, who have had much experience of the use of vaccines in the treatment of typhoid fever, declare that the results are not especially striking, while others have found them to be practically negative. For example, J. B. Nichols[7] tried the inoculation method in the Freedmen's Hospital, but "no effect on the clinical conditions, in the way of either improvement or aggravation of the symptoms, was definitely demonstrable." Richardson[2] reported the results of the method in twenty-five cases of typhoid fever without encouraging effects. He, however, asserts that the influence of inoculation is favorable in preventing, in large measure at least, typhoid relapses when its use is continued during the period of convalescence. Emery[8] remarks that the curative treatment of typhoid fever by vaccine therapy is not satisfactory and is still on trial, although he admits that promising results have been obtained by some observers.

[7] Nichols, J. B.: Washington Med. Ann., November, 1909, p. 293.

In eight cases, reported in this paper, small doses of vaccine were employed, namely, initial doses of 25 millions, and subsequent ones of 50 millions each. These were repeated at intervals of seventy-two hours, as a rule. According to some writers, a safe and useful initial dose is 300 to 350 millions of organisms; this sometimes produces a reactionary rise of temperature to 105 F. In my view, massive doses should not be employed in the milder forms of typhoid fever for the reasons previously adduced.

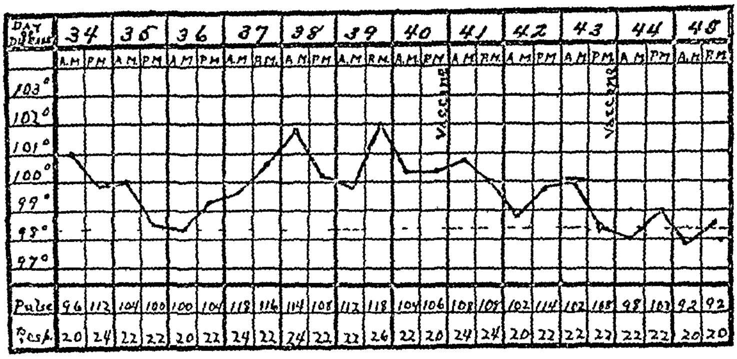

Fig. 1.—Temperature chart, case of B. M., illustrating effect of vaccine treatment in typhoid fever.

In my series of eight cases, in all save one of which the Widal reaction was present, a reactionary fever did not occur; but in two instances (Charts 1 and 2), the nocturnal remissions of temperature became distinctly greater immediately after the use of the vaccines, and in one instance of protracted subfebrile temperature due to typhoid fever, it would seem that they were sufficiently powerful to cause a gradual decline of temperature to the normal in the course of several days. In a case of prolonged and exhausting illness, the patient apparently making no progress toward recovery, Ramsburgh, on the advice of Nichols, used a vaccine with definitely favorable results. Ruffin[9] has reported a case of typhoid fever with prolonged course, in which the injection of 800 million bacilli produced a sharp febrile reaction, followed by subsidence of the pyrexia. In one of my cases a relapse occurred.

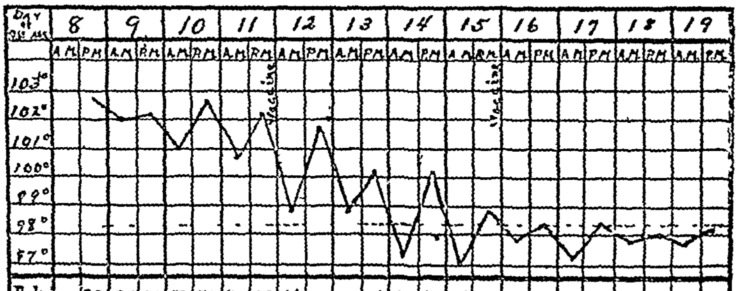

Fig. 2.—Temperature chart, case of L. W., illustrating effect of vaccine treatment in typhoid fever.

A blood examination in my series of cases before injection of vaccines and another twenty-four hours thereafter gave an average result, as shown in the accompanying table.

In view of the fact that phagocytosis most probably plays a principal rôle in Nature's method of curing typhoid fever, the question of the effect of vaccines on the leukocyte count should not be ignored. I am not aware that this aspect of the subject has been investigated hitherto, but it seems to me to be one quite worthy of further consideration. It is clear, if the foregoing premises be correct, that an increased production of polynuclear leukocytes must stimulate, to a corresponding extent, the phagocytosis of the intruding organisms of this disease. But though my own observations, which are too few to warrant generalization, show that small doses of vaccines do not, to any appreciable degree, stimulate phagocytosis during typhoid fever, it is desirable also, to note effect of larger doses.

Finally, it must be conceded that in the complicated process of active immunization, other, although doubtless minor, factors enter. For example, Nuttal and other observers found that "bacteria underwent changes indicative of death and destruction before they were taken up by the phagocytes" (Emery). It will not be denied that serum is an aid to phagocytosis by its action on the bacteria; hence opsonins are believed to be specific antibodies.

Granted that active immunity in typhoid fever is brought about mainly by an increase in opsonins circulating in the blood, it must be recollected, as pointed out above, that bacteriolytic antibodies set free the endotoxin of the typhoid bacilli, and hence may be a source of added danger. Under these circumstances, bacteriolytic serums can scarcely be regarded as Nature's means of establishing immunity.

If, however, as before stated, the process of immunization is dependent chiefly on phagocytosis, and if it be shown that the vaccines stimulate the bone marrow to an increased production of leukocytes, and, through chemotaxis, also, cause an increased output of these cells, then vaccine therapy is to be advised and encouraged.

The mobilized defensive forces in a case of typhoid fever, however, would seem to center about phagocytosis. In this connection, the fact that leukopenia exists in

[8] Emery: Immunity and Specific Therapy, pp. 390-391.
[9] Ruffin: Washington Med. Ann., 1909, viii, 77.

uncomplicated typhoid fever is to be recollected. At all events, in view of the foregoing facts, the use of vaccines in the treatment of this disease should be somewhat restricted according to conditions and indications presented by individual cases. Their routine use, however, is not to be encouraged, but it is obvious that an anti-endotoxin serum would, by neutralizing the soluble endotoxins, constitute the ideal method of treating typhoid fever. Such a serum has been prepared by MacFadyen, and favorable results have already been reported from its use, when administered early in typhoid cases. It is not improbable that the vaccine treatment of typhoid fever, except as indicated below, will give place to the method of establishing passive immunity by means of an anti-endotoxin. In view of the marked discrepancy among clinical observers as to the size and repetition of the doses, there would seem to be great necessity for an especial consideration of these aspects of the question of therapeutic inoculations in the future.

Vaccine therapy in the treatment of typhoid fever, however, should receive a more extended trial than hitherto, more particularly in the earlier stages of mild types of the disease, before being rejected. Finally, in the present state of our knowledge, the value of vaccines for the following purposes must be conceded: (1) as a means of prophylaxis; (2) in suitable cases when continued during convalescence, to prevent relapses; (3) to combat local infections with the typhoid bacillus, as for example, bone suppurations which arise in the period of convalescence, and (4) for the removal of the typhoid bacilli from the feces and urine in the case of typhoid-carriers.[10]

I desire to express my thanks to Dr. A. A. Stevens, who at my suggestion, treated three of the cases reported above with the results of blood examinations before and after the inoculations, in the wards of the Protestant Episcopal Hospital of Philadelphia, and to Dr. Robert B. Walker for furnishing one of the cases belonging to my series from the Philadelphia Hospital.

1605 Walnut Street.

THE FUNDAMENTAL PRINCIPLES UNDERLYING THE TREATMENT OF WOUNDS ON THE BODY SURFACE

CHAUNCEY E. TENNANT, M.D.
DENVER

Steadily through the maze of a multiplicity of methods, there has crystallized the present treatment of surface traumatic lesions. Based on the knowledge of definite pathologic and histologic processes and confirmed by the shorter periods of disability and lessened distortion of function, modern treatment of surface injuries may be reduced to two fundamental principles: *moist hyperemia* and *the open-air treatment;* in other words, the use of a dressing capable of giving sustained heat and moisture, or one so constructed that it will not displace the protective covering of coagulated serum, yet will protect the wound from further damage.

The wide latitude of pathologic possibilities in surface lesions, varying as they do from a microscopic skin puncture attended with violent constitutional toxemia and death, on the one hand, to extensive abrasions and lacerations with no constitutional manifestations on the other, has, in a measure, justified any course which has had as its result a satisfactory functional termination.

Until recently, little thought was given to the individual factor of lowered bacterial resistance, or the influence of the general state of nutrition on cell-regeneration. But now, with the more careful and detailed consideration of the possibilities of lowered resistance and cell nutrition, there has been a stimulus for the introduction of methods calculated either to intensify locally, or to increase, the number of antibactericidal bodies at the various parts of the organism where needed, or to engorge the tissues with nutritive plasma for the revitalization of the traumatized cell.

Surface lesions of the body widely differ in character, as burns, incised or crushing wounds, etc., and they may also vary from the small pin-point puncture to the extensive loss of continuity which is limited only by the size and force of the destructive agent. But so far as the end-results are concerned, the only difference is their type and degree of infection. Therefore the plan of treatment must be early outlined, if the most successful results are to be obtained. It is well known that in burns, skin-grafts and other superficial traumas which remain sterile, the dry method of treatment gives the most satisfactory results both as to convalescence and function, while the moist hyperemia is the treatment especially adapted to infected wounds, where the organism has lodged itself in the subcutaneous tissues and lymphatics.

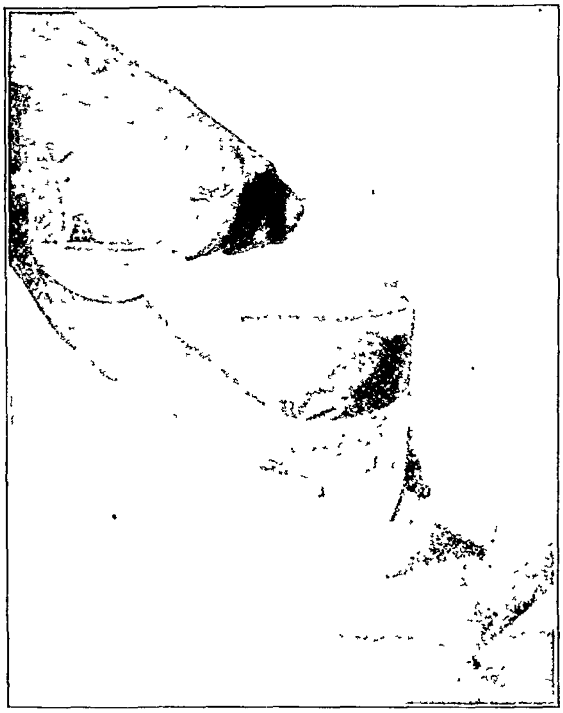

Fig. 1.—Method of applying large and copious wet dressings.

As a rule, the infection is either of the staphylococcic or streptococcic type; the former invariably localizes in a small area, while the latter is most likely to lodge in the subcutaneous tissues and extend rapidly along the lymphatics. Where resistance is fair and early excited, the chemotactic disturbance is quickly manifested with temperature and other clinical phenomena of inflammation. In either type of infection, it is extremely imporof the method in twenty-five cases of typhoid fever without encouraging effects. He, however, asserts that the influence of inoculation is favorable in preventing, in large measure at least, typhoid relapses when its use is continued during the period of convalescence. Emery[8] remarks that the curative treatment of typhoid fever by vaccine therapy is not satisfactory and is still on trial, although he admits that promising results have been obtained by some observers.

DENVER

Steadily through the maze of a multiplicity of methods, there has crystallized the present treatment of surface traumatic lesions. Based on the knowledge of definite pathologic and histologic processes and confirmed by the shorter periods of disability and lessened distortion of function, modern treatment of surface injuries may be reduced to two fundamental principles: *moist hyperemia* and *the open-air treatment;* in other words, the use of a dressing capable of giving sustained heat and moisture, or one so constructed that it will not displace the protective covering of coagulated serum, yet will protect the wound from further damage.

The wide latitude of pathologic possibilities in surface lesions, varying as they do from a microscopic skin puncture attended with violent constitutional toxemia and death, on the one hand, to extensive abrasions and lacerations with no constitutional manifestations on the other, has, in a measure, justified any course which has had as its result a satisfactory functional termination.

Until recently, little thought was given to the individual factor of lowered bacterial resistance, or the influence of the general state of nutrition on cell-regeneration. But now, with the more careful and detailed consideration of the possibilities of lowered resistance and cell nutrition, there has been a stimulus for the introduction of methods calculated either to intensify locally, or to increase, the number of antibactericidal bodies at the various parts of the organism where needed, or to engorge the tissues with nutritive plasma for the revitalization of the traumatized cell.

Surface lesions of the body widely differ in character, as burns, incised or crushing wounds, etc., and they may also vary from the small pin-point puncture to the extensive loss of continuity which is limited only by the size and force of the destructive agent. But so far as the end-results are concerned, the only difference is their type and degree of infection. Therefore the plan of treatment must be early outlined, if the most successful results are to be obtained. It is well known that in burns, skin-grafts and other superficial traumas which remain sterile, the dry method of treatment gives the most satisfactory results both as to convalescence and function, while the moist hyperemia is the treatment especially adapted to infected wounds, where the organism has lodged itself in the subcutaneous tissues and lymphatics.

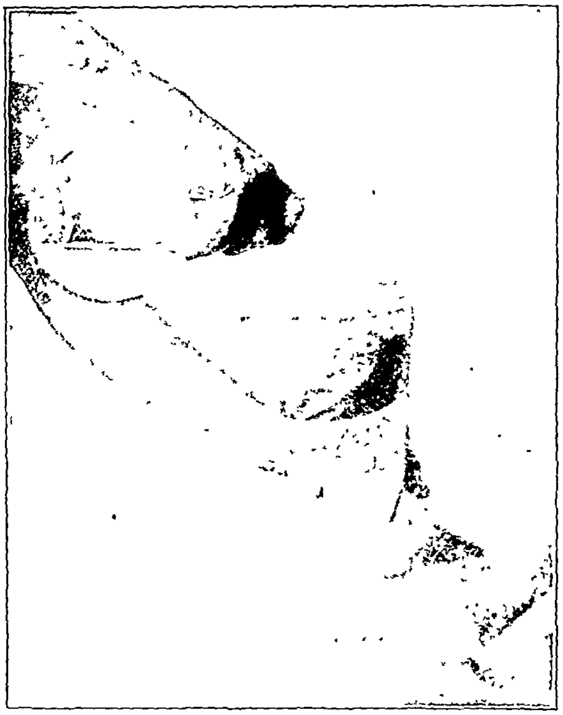

Fig. 1.—Method of applying large and copious wet dressings.

As a rule, the infection is either of the staphylococcic or streptococcic type; the former invariably localizes in a small area, while the latter is most likely to lodge in the subcutaneous tissues and extend rapidly along the lymphatics. Where resistance is fair and early excited, the chemotactic disturbance is quickly manifested with temperature and other clinical phenomena of inflammation. In either type of infection, it is *extremely impor-*

tant, as soon as it becomes evident that a pathogenic organism has lodged in the subcutaneous tissues and that the resistance force is low, that these natural forces be augmented by either the active or passive hyperemic process, or both. Every effort must be immediately made to create an overwhelming quantity of polymorphonuclear neutrophils and leukocytes to inhibit and digest the invading organisms before they have time to extend into the surrounding structures.

In all injuries involving a break in the skin, the first question to be determined is the presence or absence of infection, and if there is infection, whether or not the individual has sufficient resistance to destroy the organisms quickly providing moist hyperemia is properly used.

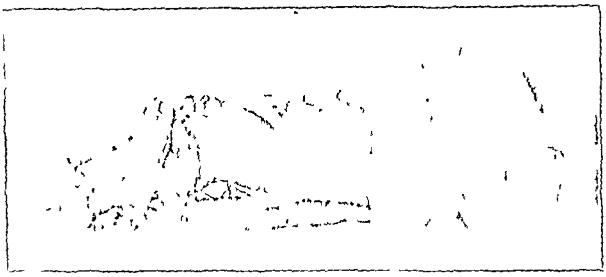

Fig 2

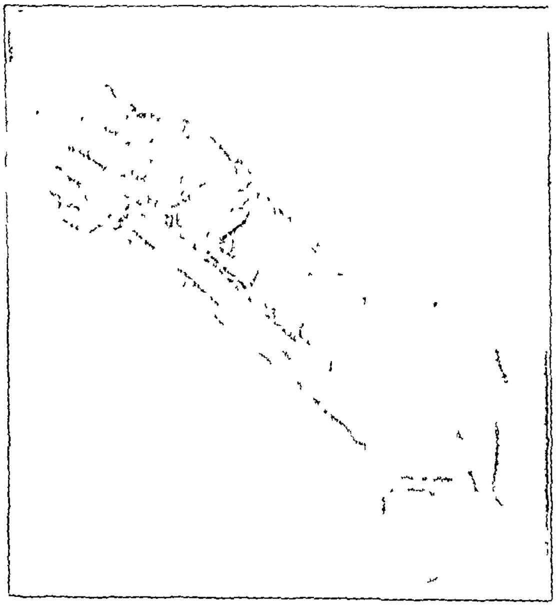

Fig. 3

Figs 2 and 3—Sheet of light aluminum to which is fastened a strip of poultry wire.

The time is not long past when all these wounds were considered as primarily infected, and vigorous steps were immediately taken to rid the host of the unwelcome guest. Active antiseptics were freely used, most of which were destructive alike to tissue and invading organism, and, as a result, tissue necrosis with moist surfaces, sloughs, granulations and large cicatrices was the common sequence.

At the present time, the practice of putting every injury in wet dressings, or even the use of copious washings, is uncalled for; especially as the coagulated serum is extremely soluble in water, and such procedure means the removal of Nature's protective layer of coagulation from the surface, and a portal left open for infection. The care of these cases, requires of course, considerable judgment, but why modern surgery should find any more reason for vigorous and persistent cleansing of these surface lesions than in the case of gunshot wounds of the extremity seems a question worthy of consideration.

If it is good practice to put gunshot wounds up in sterile dressings and wait for further evidence of infection, why should not the same principle apply to other reasonably sterile and easily accessible traumas of the surface? Where the history of the case shows a strong probability of there having been infectious material introduced into the wound, then great care should be used and proper application of the wet dressings made, with full knowledge of the fact that Nature's protective barrier must be sacrificed in the use of moisture.

We know that wherever infections occur, the use of moist dressings properly applied, quickly raises the polymorphonuclear neutrophilic blood content, which soon overwhelms the invading organism. Where no infection exists, the dry dressing, properly applied permits of surface coagulation of the exudates, which forms both a splint and an impervious barrier to further infection. Repair is very prompt in these latter cases if destructive antiseptics have not been used. Here the moderate application of sterile warm water and a bland soap, followed by open-air dressings, is usually all that is necessary to accomplish rapid and uncomplicated repair. Even in the greasy dirt-begrimed hands of the machinist, where it is not possible to wash the wound, the application of either turpentine or the tincture of iodin is very practical and effective, and may be safely followed by the dry dressing.

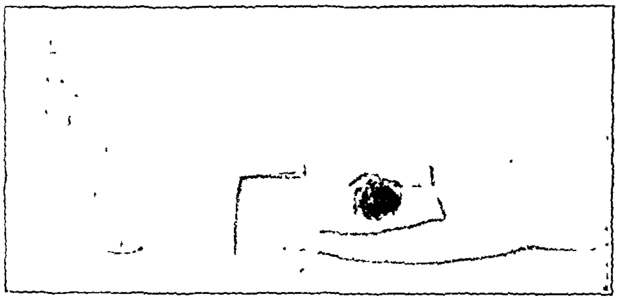

Fig 4—Copper or aluminum coated fly screen bound with adhesive tape.

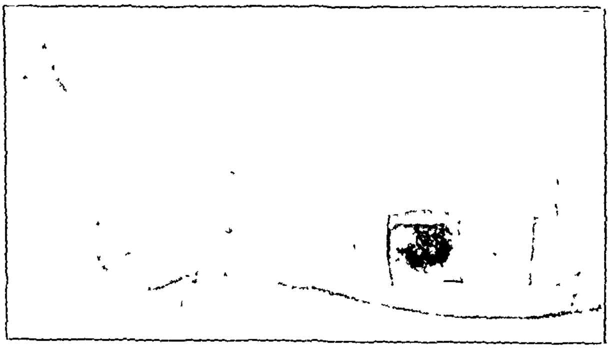

Fig 5—Adhesive straps are then passed over the screen, holding it firmly to the adhesive sheeting

The day of the local applications of salves and dressing powders in emergency surgery, fortunately, has passed. If the indications for *the treatment of these* cases are properly interpreted, and the principle underlying the use of moist hyperemia or open air is fully comprehended and applied, the profession at large will greatly reduce the number of general septicemias. Where infection is definitely present, free incision must of course be made, and followed by the application of very large and copious wet dressings, consisting of, first, the gauze covering the site of the lesion and near-by tissues, then several layers of cotton, and finally the oiled silk, moisture and bandage (Fig. 1).

If a finger only is involved, the entire hand should be included in the dressing, so that the full benefit of the hyperemia may be secured. When the oiled silk has been well fastened down, a last small opening should be left, through which the hot fluid is poured until the dressings are supersaturated. After this, the oiled silk should be completely closed, to retain both moisture and heat. A splint should then be applied to keep the part at rest. Extreme care must be exercised that the solutions poured into the dressings are not too hot, for extensive burns may easily be produced, which are often more serious to care for than the original lesion.

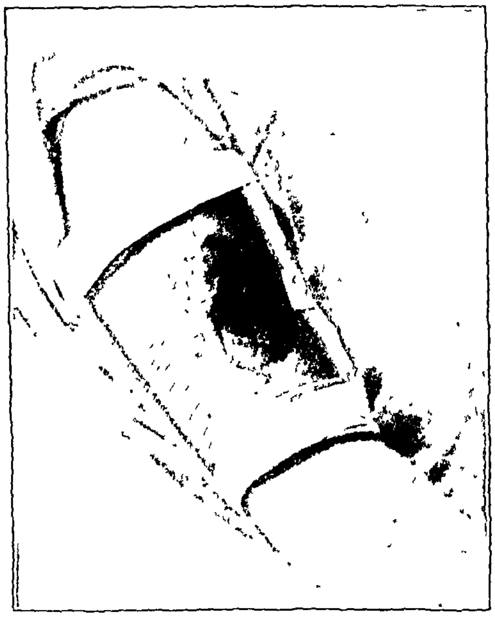

Fig. 6.—A very satisfactory dressing in skin grafting and varicose ulcers.

Several solutions may be used to moisten these dressings, the simplest and safest of which is the hot sterile physiologic salt solution. Equal parts of alcohol and saturated solution of boric acid make a solution which is ideal for use in early dressings, because of its local stimulating effect on the tissues, which produces an active local hyperemia. Thiersch's solution (salicylic acid, one-half dram, boric acid, 2 drams and a quart of sterile water), so well recommended by the late Nicholas Senn, is another safe and effective solution for use in the wet dressings.

Unless the dressings are large enough to retain both moisture and heat for long periods of time, they are worse than useless.

Dressings should be changed once in twelve to twenty-four hours, depending on the amount of discharge, but the solution should be repeated as often as necessary. A change of the solution is often of great advantage, especially if the alcohol has first been used, since the other named solutions are less stimulating yet almost as satisfactory as hyperemic agents. After a certain period tissues often refuse to respond to further stimulation. Where infection has not occurred, and is not likely to occur, it is much better that no dressings should come directly in contact with the wound, especially if it is extensive and moist. It has long been recognized that burns and traumas of the face, where dressings are not applied, soon heal with but little inconvenience to the patient, and a minimum of cicatrix. The same principle applied to other parts of the body works equally well. However, to devise successful methods for the application of treatment to these parts has been a difficult task, and the means at present used are almost as many as the surgeons applying them.

Two methods which I have been using for the last four years may be of interest, since they have been extremely satisfactory in my work (Figs. 2 and 3).

One is the use of a sheet of light aluminum as a base on which is fastened a cage made of poultry wire of any desired mesh for enclosing an extremity. The aluminum is light, clean, and easily punctured, yet firm enough to hold the poultry-wire top to the desired position. This frame is extremely light and comfortable, and easily applied. It is especially useful in extensive burns of the extremities.

The other is the use of aluminum-coated metal fly-screen, cut to the desired size, bound with adhesive tape, and set on strips of adhesive felt sheeting, which have first been cut, fashioned and attached to the skin about the outer margin of the wound (Figs. 4 and 5).

Adhesive straps are then passed over the screen, holding everything firmly to the part, yet nothing touches the wound (Fig. 6).

It is then covered with gauze dressings and snugly bandaged.

This last method has, in my experience, been very satisfactory in skin grafting, and in varicose ulcers of the leg. In the latter lesion, one may apply any form of medicament first, then cover with wire netting as described.

SOME EFFECTS OF BRIGHT LIGHT ON THE EYES *

J. HERBERT PARSONS, F.R.C.S.
Surgeon, Royal London Ophthalmic Hospital; Assistant Ophthalmic Surgeon to University College Hospital
LONDON, ENGLAND

It is my first and most pleasing duty to express to you my high appreciation of the very great honor you have done me in inviting me to deliver this address to so distinguished an audience. It has been my good fortune to have met many of you on the occasions of your pilgrimages to the Old World. Moorfields and Vienna have long been the Mecca and Medina of ophthalmologists, and we at Moorfields are proud of the sacred fire which has been handed down to us by our predecessors. No branch of science, however, can flourish on the records of the past, and we in our turn must make pilgrimages to newer shrines, there to gather fuel to keep the sacred flame alight. I would fain believe that you in the past have learnt much from us; we too have learnt much from you. Thus in the brotherhood of science may we cement the brotherhood of race which is our inalienable heritage.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-First Annual Session, held at St. Louis, June, 1910.

I propose to speak to you to-day on some effects of bright light on the eyes. I cannot adequately traverse so large a subject in the short time available. I shall, therefore, confine my remarks chiefly to those details which have specially occupied my attention recently. We as ophthalmic surgeons are fully cognizant of many pathological conditions in which the harmful effects of bright light, natural or artificial, are manifest or may be reasonably conjectured. I need only enumerate eclipse-blindness, snow-blindness, ophthalmia electrica, lightning cataract, glass-worker's cataract, erythropia. In all these exposure to bright light plays an important if not a prepotent part. There are many other conditions in which this factor has to be taken into consideration, and we as yet know little of the prolonged effect of various sources of artificial illumination on the eyes. Engineers and others who devote their attention to artificial lighting have until recently paid little or no attention to the physiological and pathological aspects of the question. Efficiency—maximum illumination at minimum cost—has been their watchword. We opthalmologists, if we are honest with ourselves, must confess to a lamentable ignorance of the conditions which render bright light deleterious to the eyes and of the methods whereby these conditions may be ameliorated. We must set our house in order and this dusty corner must be swept and garnished.

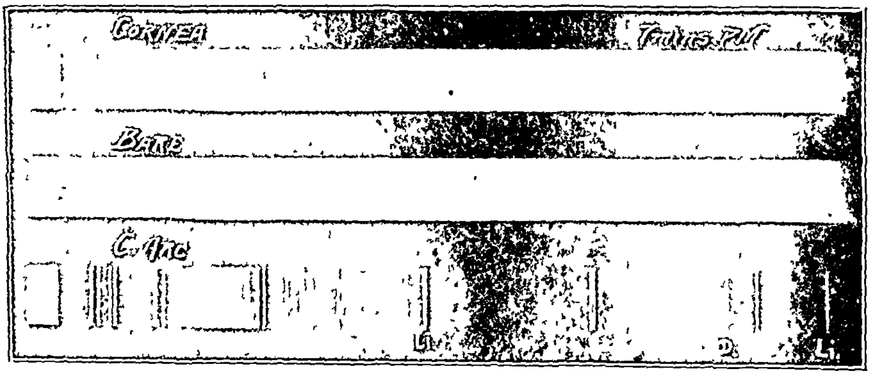

Figure 1

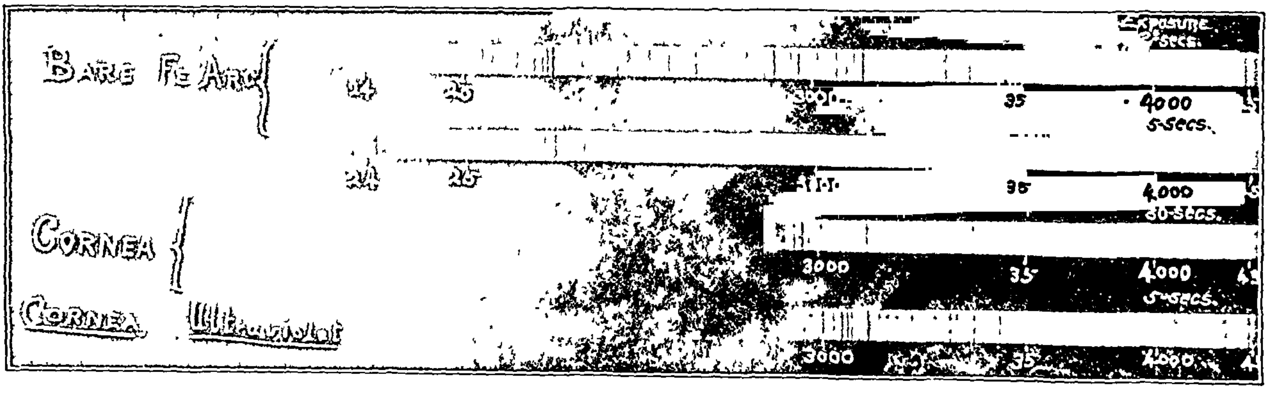

Figure 2.

Figs 1 and 2—Photographs showing spectra of cornea with carbon and bare iron with different lengths of exposure. The cornea was found to offer no resistance to wave lengths greater than 295 microns, but all those beyond this limit were completely cut off.

THE PHYSICS OF BRIGHT LIGHT

The first problem which confronts us is a physical one. What is bright light? Physiology is the knowledge of the response of the living organism to physical stimuli, and ere we can attain to certain knowledge of the inception, development and consummation of the response we must obtain accurate information of the forces which initiate it. What is generally understood by the term bright light is a composite congeries of allied manifestations of energy, comprising such apparently various forces as heat, light in the narrower sense of the word, and chemical action. Various as these forces are, they are physically identical in character, all consisting of waves of identical character, differing only in length and rapidity of vibration. Those of longer wave length cause the sensation of heat, those of shorter wave length give rise to chemical action, whilst those of intermediate wave length cause the sensation of light; but while the physical series is perfectly and mathematically uniform, the physiologic manifestations overlap and vary according to the nature and condition of the recipient organs. I may seem to you to be laboring over elementary details, but it appears to me to be of the greatest importance to bear them well in mind, as I hope now to prove. If we take ordinary sun light as the basis of our investigations it is possible to split it up by appropriate means into its component "rays," differing from each other in wave length. Of these, certain are visible and constitute light in the narrower sense of the word, but instead of giving rise to the sensation of white light they, to the majority of people, show certain pure colors, viz.: red, orange, yellow, green, blue and violet in order, the red having the longest, and the violet the shortest wave length. The visible spectrum extends from about 723 microns at the red end to 397 microns at the violet end. Beyond the red end are rays of greater wave length which cause a rise of temperature; beyond the violet end are rays of smaller wave length which are capable of causing chemical action. So striking is the physiologic phenomenon of the visibility of the intermediate series that the heat rays are commonly spoken of as "infra-red" and the actinic or chemical rays as "ultra-violet." For this reason I think that the importance of the physical uniformity of the series is obscured and is liable to be lost sight of. For example, every average normal individual is not able to see all the rays from 723 microns to 397 microns; most people see fewer, roughly from 600 microns to 400 microns. Again, though the ultra-violet rays are particularly potent in inducing chemical action, the visible rays are also actinic, though in less degree, and the same is true of the infra-red rays in still less degree. Further, the longer visible rays also cause a rise of temperature. The most convenient and most striking method of demonstrating actinicity is by the photographic film, so that we have come to regard a photograph of the spectrum as a complete analysis of the light under observation, too often forgetting that the photograph varies with the specific sensitiveness of the film to particular groups of waves. Thus, it is only by specially sensitized films, invented by Sir William Abney, F.R.S., that it is possible to demonstrate infra-red rays photographically.

Figure 4.

Figs. 3 and 4.—Photographs showing spectra of lens suspended in normal saline, in thin films and squeezed to different thicknesses, with different periods of exposure. Rays of wave lengths less than 350 microns are absorbed completely, absorption commencing at about 400 microns. Absorption varies *pari passu* with the thickness of the layer of lens substance.

It is further essential that the mode of analysis of the light under observation be unexceptionable. An ordinary spectroscope with glass prisms and lenses suffices to demonstrate the visible spectrum, and indeed with minute accuracy, but it is almost useless for showing the shorter ultra-violet rays, since these are absorbed by the glass. In order to demonstrate the full extent of the spectrum it is necessary to use a train of lenses and prisms made of quartz, which allows a maximum number of rays to pass unimpeded.

PRACTICAL CONSIDERATIONS

To come now to the practical application of these considerations to the problem before us, we must guard against presuming that the retina will act exactly like a particular photographic film; that because a light very rich in ultra-violet rays produces a particular effect on the retina or lens, that effect is produced solely by ultra-violet rays and that the visible rays play no part in the causation; that because certain rays produce pathologic changes in the retina of the aphakic eye they will produce the same changes in the normal eye—they may be absorbed by the lens; and so on.

From what I have already said it should be obvious that the next point in logical sequence in our investigation should be the determination of the absorptive capacity of the various dioptric media of the eye for particular rays of the solar spectrum. There is an additional reason in favor of this procedure in that the absorption of energy means simply the transformation of energy, and it may be that the transformed energy is exerted deleteriously on the organ under investigation. Thus the absorption of particular rays by the lens may be the cause of pathologic changes in that structure. But before passing on to this question it will be well to describe the nature of the rays emitted by various sources of artificial illumination, partly because it is more convenient to use some of these in experimental investigations than sunlight, and partly because we wish to find out if these have any deleterious effects, and if so, their nature and cause.

THE SPECTRA OF ARTIFICIAL LIGHTS

The spectra of artificial lights show a remarkable variety in the range of rays emitted. They have been investigated by many observers, notably recently by Schanz and Stockhausen and Hallauer. Schanz and Stockhausen's observations unfortunately do not give accurate limits of the spectra in wave-lights. It will suffice to state roughly the limits of a few of the commoner lamps used for ordinary illumination or for experimental purposes. A petroleum lamp with an ordinary white glass cylinder gives a spectrum from 600 microns to 350 microns; osmium and tantalum lamps from 630 microns to 300 microns, an Auer incandescent gas lamp with glass cylinder from 600 microns to 329 microns, an arc lamp with clear globe from 600 microns to 300 microns, the same lamp without any globe from 600 microns to 230 microns; with an opal globe down to about 330 microns. The Schott uviol mercury vapor lamp, in which incandescent mercury vapor is contained in a long tube made of a special quartz-glass gives forth ultra-violet rays down to 253 microns, but is poor in red and yellow rays.

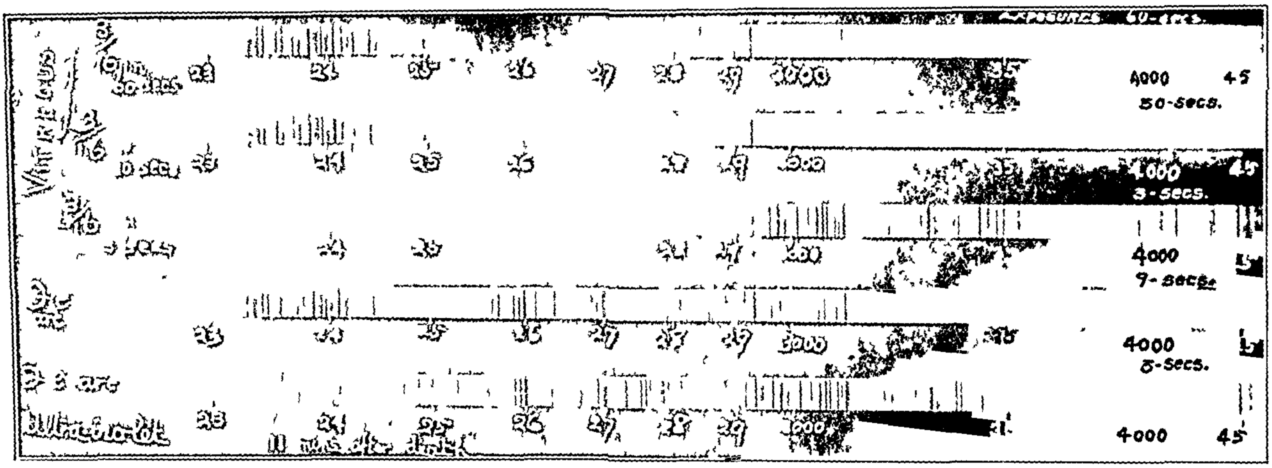

Figure 5

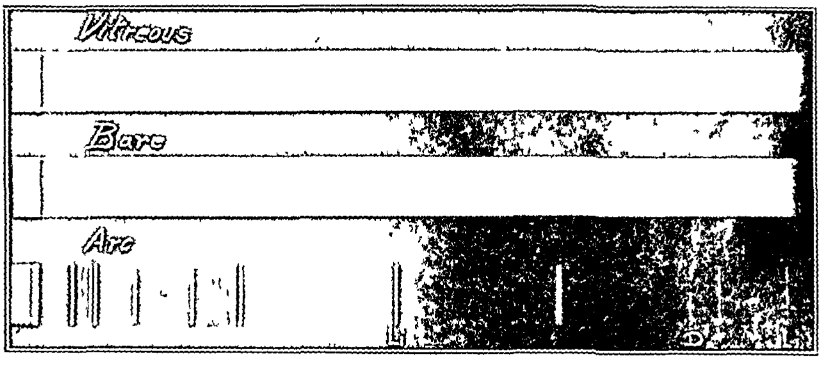

Figure 6

Figs. 5 and 6.—Photographs showing spectra of vitreous. The vitreous in a layer 3/16 inch thick shows a broad absorption band extending from 280-250 microns, with a maximum at 270. The margins of the band are ill defined. Exposures for different periods as shown.

ABSORPTION BY THE DIOPTRIC MEDIA

Passing now to the absorption of light by the dioptric media of the eye we have to investigate the cornea, lens, and vitreous. The aqueous acts like water and causes very little absorption of visible or ultra-violet rays. Like water, too, it absorbs heat strongly, so that it is improbable that even with exposure to extreme heat such as is met with in iron works and glass works much heat reaches the lens. More experiments, however, are needed on this point and it is unjustifiable to be dogmatic in the present state of our knowledge.

EXPERIMENTS

I made some experiments two years ago on the absorption spectra of the cornea, lens and vitreous of the rabbit with Messrs. E. C. C. Baly, F.R.S., and E. E. Henderson. These have since been extended and confirmed by my assistant, Dr. E. K. Martin.

In this research experiments were made to determine the precise limits within which rays are absorbed by the refractive media of the eye, and the effect on these limits of keeping the media some hours after the death of the animal. Young rabbits were used in all cases.

The spectrophotographic method of recording the results was used and the media were mounted in cells with parallel sides. In the case of the cornea and vitreous the cell was placed close to the slit of the spectroscope. The lens was dealt with in two ways:

1. Suspended in normal saline and placed at a distance from the slit greater than its focal length, so that a blurred image of the source of light was thrown on the slit. This was necessary to avoid horizontal lines on the resulting photograph; the precautions taken quite excluded the possibility of stray light entering between the cell and the slit.

2. A thin layer of lens substance was squeezed out flat between the parallel sides of the cell; this was done to eliminate any possible apparent absorption due to the shape of the lens.

A preliminary series of spectro-photographs was taken to eliminate absorption within the limits of the visible spectrum. In this the source of light was the crater of a carbon arc and a 2-prism spectroscope was used, the prisms and lenses of the instrument being of glass.

The plates used were "orthochromatic," and it was found that they regularly showed three faint absorption bands in the green, yellow and red. These represent the absorption of the dye used to sensitize the plates to red light.

All the media were found to be uniformly permeable to rays between the wave lengths 660-390 microns. (The visible spectrum extended from approximately 760-380 microns.)

For the ultra-violet rays the iron arc was the source, and quartz was used throughout. Ordinary plates were used, i. e., plates containing no dye and hence giving no absorption bands. The range of wave lengths covered in this series was 450-230 microns.

Cornea. The cornea was found to offer no resistance to rays of wave-lengths longer than 295 microns, but all those beyond this limit were completely cut off.

Lens. (a) Suspended in normal saline. Rays of wave-lengths less than 350 microns are absorbed completely. The line is not a sharp one, the absorption commencing at about 400 microns.

(b) Squeezed to different thicknesses. The absorption varies *pari passu* with the thickness of the layer of lens substance.

Vitreous. The vitreous in a layer 3/16 inch thick shows a broad absorption band extending from 280 to 250 microns, with a maximum at 270 microns. The margins of the band are ill-defined.

These results agree closely with those recently obtained of Schanz and Stockhausen and Birch-Hirschfeld.

The shortest interval between the death of the animal and the taking of the observation was three minutes, the longest eleven minutes.

Observations were also made on the vitreous 1 hour, lens 5 hours, and cornea several hours after the death of the animal. The results obtained were identical with those from fresh specimens.

The photographs were taken at the Imperial College of Science and Technology, South Kensington, those of the visible spectrum in Sir William Abney's laboratory, the ultra-violet series in the astrophysical laboratory by kind permission of Professor Fowler, F.R.S., to whom I am indebted for valuable suggestions.

OTHER EXPERIMENTAL OBSERVATIONS

It would be unsafe to apply these results, obtained with rabbits' eyes, directly to the human eye. As regards the cornea and vitreous observations of a similar nature made by Schanz and Stockhausen on the calf's eye are confirmatory. Birch-Hirschfeld has similarly investigated the eyes of calves, pigs and oxen. He found little difference in the absorption of ultra-violet rays by the cornea, giving the limit as 306 microns, somewhat higher than for the rabbit, and rather more than that of ordinary glass, the limit of which may be taken as 300 microns. In all cases too Birch-Hirschfeld found the limit of absorption to be 300 microns for a layer of vitreous 1 cm. thick. Greater differences which cannot be neglected were found with various lenses. Those of the rabbit's lens varied between 330 microns and 390 microns. For the pig's lens the average limit was 330 microns with variations of about 15 microns; for the calf's 328 microns, with variations of 12 microns; for the ox lens from 270 microns to 400 microns.

Schanz and Stockhausen examined the cornea and lens of a child who had glioma. They do not give accurate wave-lengths, but the cornea absorbed up to nearly 300 microns, and the lens about the same; whereas in a case of injury, whilst the corneal absorption was about the same, that of the lens was much greater, up to about 350 microns.

Hallauer has recently found that the corneal and vitreous absorption in the eye of a man of forty extended to 295 microns. He has examined a large series of human lenses from individuals of different ages and has arrived at some valuable conclusions. He finds the limits of absorption on the whole dependent on age, with some individual variations due to thickness, color and consistence, general disease also introducing a disturbing factor, which must be taken into account in Schanz and Stockhausen's case of glioma. In babies and children absorption extends to 400 microns, often combined, however, with an inability to absorb rays from 300 to 310 microns. This transparent band persists up to about the twentieth year and may be more extensive in debilitated conditions. *Pari passu* with the loss of this band after twenty the limit of absorption retracts to about 377 microns, but extends with advancing age to 400-420 microns; extreme debility from disease diminishes absorption to a minimum of 375 microns.

From these investigations it will be seen that the lens has a very powerful capacity for absorbing ultra-violet rays. This fact is indeed easily and strikingly demonstrated by the strong fluorescence which occurs when these rays fall on it. Schanz and Stockhausen attribute the fluorescence to rays between 400 microns to 350 microns, but as Helmholtz pointed out, a fluorescent body always absorbs strongly those rays which induce the fluorescence. Hence the chief rôle must be allotted to rays between 350 microns and 300 microns, for those from 400 microns to 350 microns are absorbed to a relatively slight extent by the lens. Another fact pointed out by Helmholtz, that the light emitted by fluorescing bodies is of longer wave length than that which causes the fluorescence, confirms this view. Fluorescence is indeed a degradation of invisible ultra-violet rays to rays of the visible spectrum. The investigation of this question is not unattended with complicating features, especially those due to fluorescence of the observer's own lenses.

PATHOLOGIC CHANGES PRODUCED

Whatever be the exact limits of the ultra-violet rays which are capable of causing the crystalline lens to fluoresce, there is no doubt about the fact, nor that such rays are absorbed by the lens. It is not, therefore, illogical to conjecture that these rays may produce pathological changes in the structure. For this reason, in conjunction with Mr. E. E. Henderson, I have exposed rabbits' eyes for prolonged periods to the light from Schott's uviol mercury vapor lamps. Similar experiments have been made independently by Hess, Birch-Hirschfeld, and others. As already stated, these lamps emit ultra-violet rays down to 253 microns. Four tubes were used and the rabbit's eyes were situated about 20 cm. from them, exposures of one to four hours being made repeatedly two or three times a week for several weeks. At the distance used the rise of temperature is negligible. It should be noted that the eyes were exposed not only to the ultra-violet, but also to the visible rays. Even with the longest exposures no definite opacification of the lens was observed ophthalmoscopically, nor even on examining the lens macroscopically after killing the animal. After hardening in Zenker and examining the anterior capsules microscopically, however, changes could be seen in the anterior capsular cells. These changes have been well described and illustrated by Hess, and our conclusions as to their appearances are in agreement with his.

When the capsule, stained with hematoxylin and eosin is spread out and examined the most noticeable feature is the marked difference between the capsule cells in the pupillary area and those immediately surrounding this area. The nuclei of those exposed are swollen and their chromatin stains badly; the cytoplasm may be vacuolated. In the surrounding zone, behind the pupillary margin of the cornea, the cells are very closely packed together. The nuclei are small and the chromatin stains deeply. There may be mitoses in this area as well as still more peripherally. It is probable, as Hess conjectures, that the crowding together of the anterior capsule cells behind the iris is purely mechanical due to the swelling of those in the pupillary area, and is not caused by any compensatory regeneration. In some of his specimens it led to actual multiplication in the layers and heaping up of the anterior capsule cells.

Changes similar to those described were observed by Widmark after exposure to light from the arc lamp. Hess found that the changes did not occur if a glass plate which absorbed the rays of smaller wave length than 300 microns, was interposed between the lamp and the eye. I am not convinced of the accuracy of this observation. Examination of control capsules shows that the changes are rather those of degree than absolutely abnormal phenomena. More work on the dark-adapted eye is needed to settle this point conclusively. Hess considered that the experiments prove that the changes are due to rays of smaller wave length than 300 microns. But, as already stated, there is ample evidence to show that such rays do not reach the lens, being absorbed by the cornea. No similar experiments in which the visible rays, i. e., those of greater wave length than 400 microns are cut off, (only those between 400 microns and 300 microns being allowed to fall on the lens), have been carried out. It is most probable that the changes are due partly to ultra-violet rays of greater wave length than 300 microns and partly to rays of the visible spectrum. We have here a further example of the necessity for bearing well in mind the fundamental fact of the physical continuity and similarity of the rays of the visible and of the ultra-violet spectra.

CHANGES IN THE LENS—BOTTLE-MAKER'S CATARACT

Many pathologic changes in the lens in which bright light may be, or at least has not been disproved to be, an important etiological factor will occur to you. I do not propose to discuss this factor in the causation of senile cataract. Schanz and Stockhausen attribute to it a preponderant rôle. In this I think they go far beyond the bounds which the scanty evidence at present available warrants. I will confine my remarks to glass-workers' cataract, which occurs under conditions of exposure to intense glare and in which the influence of bright light has at any rate to be eliminated before we can arrive at a just conclusion as to its causation. Attention was first directed to the prevalence of cataract in glass-blowers by Meyhöfer of Görlitz in 1886. Much additional information was brought forward in 1888 in an inaugural dissertation by Röhlinger of Munich Since that date papers have been published by Cramer of Kottbus, Robinson of Sunderland, Snell of Sheffield, and others. In 1907 the British Home Office published a valuable report by Dr. Morison Legge, H. M., Medical Inspector of Factories, who confirmed the prevalence of the disease in this class of workmen, doubt having been expressed on the point by Snell. The matter came under the consideration of the Departmental Committee appointed in 1906 to schedule industrial diseases for the purpose of the Workmen's Compensation Act (1906). As a result the Home Office approached the Royal Society in 1908 with a view to their appointing a committee to investigate the physical and physiologic problems involved. A committee, consisting of physicists, physiologists and ophthalmologists, the latter including Mr. E. Nettleship, the late Mr. Marcus Gunn, whose recent loss we all deplore, and myself was appointed. In the autumn of 1908 a subcommittee, including Mr. Marcus Gunn and myself, visited some of the most important glass-works in Sunderland, Gateshead, and St. Helens. Such clinical investigation as we were able in the short time at our disposal to carry out seemed to prove conclusively that bottle-makers are subject to a form of cataract which appears to be characteristic and is unlike other forms of cataract commonly observed. In its typical form there is a dense, well-defined disc of opacity in the center of the posterior cortex. Not infrequently slighter hazy opacities are seen around the posterior cortical disc. Makers of pressed glass articles may also show cataractous changes in the lens. The typical condition, however, was seen in only one case, out of five of the selected cases examined, the remainder having forms of cataract differing in no respect from those not infrequently seen in elderly persons. Some of the patients examined showed deficiency in the power of distinguishing violet. It is not improbable that prolonged exposure to the conditions of work causes changes in the excitability of the retina. (The observations of Birch-Hirschfeld on defects of color sensation and in the color fields in cases exposed to the action of mercury-vapor lamps are interesting in this connection.) We were unable to examine any patients who worked in plate-glass manufactories. There is reason to believe that they also suffer from the disease.

Investigation of the physical conditions in glass bottle manufacture has been carried out by Sir William Crookes, F.R.S., for the Royal Society Committee, and by Schanz and Stockhausen. The materials are melted in a large fire-brick tank, heated by incandescent gas and air playing over the surface. The area of the tank is about 82 square yards and it contains some 300 tons of "metal." The tank is divided into two unequal parts by a fire-clay partition, having at the lower part an opening through which the melted glass can flow. The "working end" has an area of about 19 square yards. The temperature at the "melting end" is probably about 2,000 C., that at the working end 670 C. Schanz and Stockhausen found that the temperature at the place where the worker takes the molten metal from the tank is about 110 C.; the intensity of the light falling on his eyes is about 540 Lux.

Spectro-photographic investigation shows extension of the spectrum at each end with increased length of exposure. A photograph with twenty minutes' exposure includes wave lengths 452 microns to 690 microns; with one hour exposure, 364 microns to 760 microns; with three hours exposure, 334 microns to 780 microns. The ultra-violet area is, therefore, limited to rays of comparatively long wave length, but it is probable that this varies with the exact composition of the "metal" used. The heat rays at the red end are extremely powerful.

Exposure of sensitive films wrapped in black paper and lead foil in which designs had been cut showed complete absence of x-rays even after prolonged exposure.

Schanz and Stockhausen conclude from their observations that glass-workers' cataract is due to ultra-violet rays. In my opinion the experiments are by no means conclusive in either direction. It is certain that most of the ultra-violet rays emitted by the molten glass will be absorbed by the cornea, only relatively few of those of shorter wave length reaching the lens at all. The problem is an extremely difficult one, for it is certain that the disease occurs only in men who have been engaged at the work for many years. It is most commonly found in "finishers," experienced men who have been through all the stages of bottle-making ("taker in," "wetter off," "gatherer," "blower") and who are engaged in putting the rings on the mouths of the bottles. These men work close to the furnace, taking the metal from the tank, applying it to the mouth of the bottle, and fashioning it to the required form with a mould. They are continually looking into the furnace or at the mass of glowing, viscid glass. A finisher can do from 50 to 120 dozen bottles a day. Only the best workmen are promoted from blower to finisher. The cataract occurs also among the gatherers who collect the requisite amount of metal from the tank on the blowpipe, and the blowers, but only if they have been long engaged in the trade. Blowers have always previously been gatherers, so that both classes have usually been long engaged in an operation which requires looking repeatedly into the furnace and at the gradually cooling mass of glass.

It is extremely difficult to devise conclusive experiments for the elucidation of a problem in which the causal agent acts slowly over a very prolonged period, and until further experiments have been made to eliminate the heat factor it would be unwise to make any dogmatic statement as to the true cause of glass-worker's cataract.

EFFECTS ON CONJUNCTIVA

The diseases which I have already touched on by no means exhaust the list of those attributable to bright light and ultra-violet rays. One of the chief difficulties which we have to contend with in experimental exposure of the eyes of animals to light rich in ultra-violet rays, is the intense congestion and inflammation of the conjunctiva which is soon brought about. The irritation does not manifest itself until a latent period of some hours has elapsed, but is much aggravated by repeated exposures, so that finally the cornea is almost covered by the chemosed conjunctiva and swollen lids. The experimenter himself is not immune from this intense conjunctivitis, which is encountered also among photographers using mercury-vapor lamps, men engaged in testing photometrically naked arc lights, and so on. Complete protection is afforded by wearing plane clear glass spectacles, or, in the case of experiments on animals, by interposing a plate of glass between the animal's eye and the source of light. Since ordinary glass cuts off all the ultra-violet rays of shorter wave length than 300 microns, whilst permitting the visible rays to pass almost unimpeded, it must be concluded that the irritation is caused by ultra-violet rays of lower wave length than 300 microns. Exactly the same clinical manifestations have long been known after exposure of the unprotected eyes to light reflected from vast surfaces of snow. There is every reason to believe that "snow blindness" is due to the same cause, since at high altitudes fewer ultra-violet rays are absorbed by the atmosphere and more are reflected from the brilliant white surfaces. The same rays are responsible for "sun burn," and a striking demonstration of the absorptive capacity of the crystalline lens for these rays is shown by placing a crystalline lens on the skin and then exposing it to intense sunlight. When the "sunburn" develops, a white spot of unaffected skin marks the place where the lens lay. "Ophthalmia electrica" is of exactly the same nature as "snow blindness" and is due to the same cause.

OTHER EFFECTS

Birch-Hirschfeld has reported cases which tend to prove that exposure to light rich in ultra-violet rays is not without effect on the normal retina, so that minor defects in the color fields are produced. He found in experiments on animals that such light produced definite changes in the ganglion cells and the cells of the nuclear layers, resulting in chromatolysis, vacuolation of the cells, etc. changes which were much increased in eyes rendered artificially aphakic.

The red vision which is often so troublesome a symptom after exposure to bright light in persons who have been operated on for cataract has also been attributed to the action of ultra-violet rays. Erythropsia occurs, however, or may be induced in normal eyes, in which the absorptive capacity of the lens has to be taken into account, and is further said by some not to be prevented by wearing glasses, though this is denied by others. It cannot, therefore, yet be concluded with certainty that ultra-violet rays are solely responsible for this phenomenon.

PROTECTIVE MEASURES

Enough has been said to show that ultra-violet rays are without doubt deleterious to some parts of the eye and are probably so to other parts under certain conditions. Protection of the eyes from these rays is therefore indicated if means can be adopted which are not too inconvenient and which do not seriously interfere with the visible rays. Many observations have been made on the penetrability of various types of glass in common use, and attempts have been made to make a glass which will absorb all the ultra-violet rays without materially reducing the transparency to light. For experimental purposes maximum penetrability to ultra-violet rays is sometimes desirable. Messrs. Schott, of Jena, have manufactured a quartz glass for this purpose called "uviol." Schott's uviol crown glass (U V 3199) transmits rays down to 280 microns. It is therefore rather more transparent to ultra-violet rays than ordinary glass, though it falls very far below quartz in this respect. A few examples of the absorption of ordinary glasses may be given.

Borosilicate Crown Glass absorbs rays below 295 microns; flint glass (0.103) below 315 microns, partially 315-320 microns; ordinary blue glass below 320 microns; ordinary smoked glass below 345 microns; heavy flint glass (0.198) absorbs all rays below 375 microns, and many from 375-400 microns. Heavy flint glass therefore so far as impenetrability to ultra-violet rays is concerned meets most requirements; it is, however, quite unsuited for spectacle lenses on account of its weight.

Special glasses have been devised and placed on the market, said to absorb all the ultra-violet rays, i. e., below 400 microns. Of these the chief are "Enixanthos" glass, Fieuzal glass and "Euphos" glass (Schanz and Stockhausen). All have a greenish yellow tint, varying in intensity.

Schanz and Stockhausen assert that "Euphos" glass absorbs only 5 per cent. of visible light, but Vogt puts the figure at 25 per cent. The latter author points out that the manufacture of experimental glasses which absorb all the ultra-violet rays was accomplished long before Schanz and Stockhausen introduced their widely advertised "Euphos" glass. Eder and Valentin in 1894 made several glasses of this kind, notably a red glass containing copper oxid and others containing iron oxid. They showed that the absorption was much increased by the addition of lead to the metal. Analysis of "Euphos" glass by Dr. Werder in Aarau showed that it was an iron glass containing lead.

Sir William Crookes has recently made some valuable experiments on the diathermancy and permeability of glasses to visible and ultra-violet rays for the Royal Society Committee. Various green glasses long used in the Palm House at Kew Gardens, specially adopted because of their impermeability to infra-red rays, were examined. One of these, a very dark green glass, originally used in the ferneries, is remarkable for the short length of spectrum it transmits. It is opaque at the red end to rays longer than 579 microns and at the ultra-violet end to all rays shorter than 468 microns. On account of its color and the amount of light which it absorbs it is unsuitable as a protective glass. An almost colorless glass, tinged with didymium, is remarkable. It is opaque at the red end to rays longer than 656 microns just transmitting the hydrogen red. At the ultra-violet end it is opaque to rays shorter than 398 microns. Sir William Crookes suggests that further experiments should be carried out to include glasses tinted with other colored rare earths, as well as such metals as nickel, cobalt, chromium, uranium, etc., and also containing colorless oxids. It is noteworthy in this connection that Eder and Valentin found that ordinary cobalt glass is scarcely more absorptive of ultra-violet rays than ordinary flint or crown glass. It would appear that the almost colorless didymium glass best meets the requirements for protecting the eyes against the action of ultra-violet rays.

CONCLUSION

In any case there can be no doubt that the problem will be solved with relative ease. Much remains, however, to be accomplished in the direction of determining with greater accuracy the physiologic and pathologic potency of these rays. If I have succeeded in arousing some interest in the subject and directing the attention of others able and qualified to extend the researches, my remarks, scattered and disjointed as they are, will not have been wholly vain.

THE PHYSIOLOGIC ACTION, USES AND ABUSES OF ALCOHOL IN THE CIRCULATORY DISTURBANCE OF THE ACUTE INFECTIONS *

JOSEPH L. MILLER, M.D.
CHICAGO

The reputation of alcohol as a cardiac stimulant is as old as our knowledge of medicine. It has been a household remedy for generations and even radical prohibitionists have permitted its use for medicinal purposes. The medical profession in this country have prescribed it freely, and especially in that group of cases under consideration—the acute infections. It has been so securely entrenched in our therapeutic armamentarium that in this country, until very recent years, those who opposed its use in certain acute infections, as pneumonia, were looked on as temperance fanatics. As a preface to the present discussions the therapeutic history of alcohol in Europe during the last century is of interest.

Alcohol was so little used in Germany in the treatment of the acute infections during the middle of the nineteenth century that a physician in Coblentz was held responsible for the death of a typhoid patient for whom alcohol had been prescribed. Shortly after this, Todd, in Dublin, advocated its use in pneumonia and his teachings were quite extensively followed in the British Isles. Somewhat later Binz and his pupils, having demonstrated that alcohol was a food and reduced rather than elevated body temperature, the German clinicians, headed by Von Jurgensen, began using it extensively in febrile conditions. This wave reached its height at the Wiesbaden Congress in 1880, when alcohol was generally lauded as a valuable therapeutic agent in the acute infections. Immediately after this the experimental work of Schmiedeberg and Von Noorden and the clinical experience of Strümpell cast a shadow of doubt over its desirability, and since that time the pendulum has been swinging the other way. This is shown by the lessened consumption of alcohol in some of the large general hospitals in Europe, as, for instance, in the Vienna General Hospital, in which in 1897 $10,000 was spent for alcohol, and in 1905 this had been reduced one-half; and Cabot has shown that there is the same tendency in some of the large general hospitals in this country.

That the amount of alcohol used for medicinal purposes is on the wane does not necessarily prove that it has little value as a therapeutic agent, especially as the change in sentiment has been directly associated with a general prohibition movement.

For our purpose we must approach the subject from a different standpoint, viz.: first, the character and cause of the cardiovascular disturbances in the acute infections; second, the physiologic action of alcohol on the normal mammalian heart; third, the action of alcohol on the cardiovascular apparatus of man and animals suffering from acute infections, and finally, evidence collected from clinical experience.

It is perhaps unnecessary to mention that alcohol has some value as an antipyretic, owing to its inhibitory action in the process of oxidation (von Wendt).[1] Of more importance, and perhaps meriting a word, is its effect in combating the toxemias of the acute infections. There is still considerable difference of opinion on this point, but the recent careful experimental work of Laitinen[2] lends support to the earlier views of Koch and Doyen, that even in small doses it diminishes the bactericidal powers of the blood and lessens the animal's resistance to infection.

NATURE OF CARDIOVASCULAR DISTURBANCES

Regarding the nature of the cardiovascular disturbances in the acute infections, the early clinicians recognized the frequency of weak heart, ascribing it to the fever and parenchymatous changes in the heart muscle, first detected and described by Virchow. Somewhat later Hayem called attention to the interstitial changes and the endarteritis and thrombosis of the coronary arteries, this latter accounting for the sudden deaths met with, especially in diphtheria. Romberg was able to demonstrate a progressive acute myocarditis developing some time after the onset of the infection and continuing for some time after its subsidence. Demich attacked

the problem from the physiologist's standpoint and discovered that cardiovascular changes analogous to those present in the acute infections could be produced by section of the cord or by vasomotor poisons, such as chloral or chloroform. This led Naunyn[3] to investigate more carefully the clinical signs and symptoms of the cardiovascular apparatus in the acute infections; his results supported Quincke's theoretical views, inasmuch as the ordinary signs of weak heart-muscle, such as faint heart-tone, feeble pulse, arrhythmia and bradycardia were exceedingly infrequent, the clinical findings pointing more to disturbances in the vascular mechanism. Riegel, with the assistance of the sphygmograph and Maragliano[4] with the plethysmograph, confirmed in the main Naunyn's surmise that vasomotor factors were responsible for the disturbance. That functional disturbance of the vasomotor control plays an important rôle is further supported by the pathologists, who were often unable to find adequate anatomic changes to account for the collapse and sudden death. Furthermore, in many of these cases the conditions of the pulmonary and systemic vessels could best be explained by vasomotor paresis. To this evidence was added the effect of the acute infections in animals. Heidenhain, Charrin and Gley, Raczynski,[5] and especially Romberg and Pässler,[6] studied the effect of a number of the more common micro-organisms on the cardiovascular system. These results are so in accord that it is only necessary to refer to a few of the experiments.

Cultures of a streptococcus obtained from a case of scarlatina, when injected into rabbits, produced cardiovascular disturbance, which can best be considered in two stages. Shortly after the injection, a slight and inconstant vasodilatation could be demonstrated, leading to a slight fall in the pressure; later with approaching death the blood-pressure falls, apparently the result of vasomotor disturbances, as the heart's strength is still good, as shown by the prompt rise in blood-pressure following compression of the aorta.

Cultures of the colon bacillus behaved somewhat differently, impairment of the heart being most pronounced. The pneumococcus and diphtheria bacillus behaved in the same manner as the streptococcus, paralyzing the vasomotor center, leading to engorgement of the splanchnic circulation and underfilling of the vessels of the brain, muscles and skin. Involvement of the heart only occurred late, and then apparently secondary to nutritional disturbances caused by the vasomotor paresis. Especially in pneumococcus infections the heart remained intact to the last, this being in accord with the absence of anatomic changes in this organ after death from pneumonia.

It would appear, therefore, from clinical, anatomic and experimental evidence that the circulatory disturbances in the acute infections are chiefly vascular in origin, the heart being affected to a much less marked degree.

ACTION OF ALCOHOL IN MAMMALS

Regarding the physiologic action of alcohol in mammals, the published results would appear to be quite at variance; these apparent differences can, however, be largely explained by the method of administration and especially the dosage. Considering these points and selecting only those experiments in which methods of precision have been used, we find that the results are really in accord.

A weak solution of alcohol 0.13 to 0.3 per cent. transfused through the mammalian heart has a stimulating effect. The strength of the solution necessary to bring about a certain effect cannot be fixed absolutely. Generally speaking, however, dilutions below 0.13 per cent. are inactive and above 0.3 per cent. act as a depressant. Computing the amount of blood in man as 7 per cent. of the body weight, in order to have the above minimum in the circulating blood, would require about 7 c.c. of absolute alcohol, and for the maximum amount about 15 c.c. of absolute alcohol, or 15 to 30 c.c. of whisky. We must bear in mind that when it is administered by mouth, the delay in absorption would prevent the entire amount ingested from appearing at one time in the circulating blood. When alcohol is administered intravenously to animals, it has been shown that an amount equivalent to 0.1 to 0.3 per cent. in the circulating blood raises blood-pressure and increases the systolic output without necessarily increasing the pulse frequency (Dixon,[7] Rosenfeld,[8] Hasovec,[9] Kochmann,[10] Wood and Hoyt[11] and Bachem[12]). This rise in pressure is rather transitory, ranging from two to twenty minutes. When larger doses are given, all agree that alcohol acts as a depressant. One point of considerable significance is that it is impossible to determine beforehand in any given animal either the minimum or maximum amount required for a stimulating action.

There is still considerable difference of opinion in regard to the cause of the rise in pressure after moderate doses. Whether due to direct stimulation of the heart, the direct effect on the vessel walls, or the effect on the vasomotor center has not been definitely determined. It is certain, however, that large doses of alcohol paralyze the vasomotor center.

CLINICAL EVIDENCE

The clinical evidence relating to the value of alcohol in the acute infections may be divided into two classes, one statistical and of personal impressions, the other careful bedside study, with measured amounts of alcohol, and determination of changes in systolic and diastolic pressure, pulse-rate, etc.

Regarding the value of statistical evidence, it is only necessary to glance back over the therapy in pneumonia during the past fifty years. Laennec believed that he had a specific in tartar emetic; the advocates of venesection had their day and it was only after Skoda demonstrated that the mortality was just as low or lower when bleeding was not used, that the profession discontinued it as a general measure. The supporters of both of these measures furnished statistics that possessed the appearance of evidence. Petrescu treated 2,215 patients with pneumonia with large doses of digitalis, with a mortality of only 1.7 per cent. Aufrecht reported a mortality of 2.6 per cent. in a series of 379 cases, treated with quinin hypodermically. Results equally favorable have been reported after aspirin, creosote and iodids in large doses.

It would appear that, if purely statistical evidence were all that was required to establish a therapeutic fact, there is here sufficient proof. The error lies in the manner in which the statistics have been collected. The mortality of pneumonia is largely dependent on the age of the individual, his previous habits, the severity of the epidemic and the stage of the disease in which he comes under observation. Petrescu used his digitalis treatment on recruits—all young and healthy men—in whom the mortality would naturally be low, as Risell by pure symptomatic treatment reported a mortality of only 1.8 per cent. in 127 patients between the ages of 20 and 30 years. Statistics bearing on the value of alcohol in the treatment of acute infections are too few to permit drawing conclusions, even if free from the objections referred to. Dr. John Hay divided a series of pneumonia patients into two lots by assigning every other patient to one group. Those treated without alcohol showed a mortality of 29.5 per cent.; those receiving alcohol 45.5 per cent. We have heard a great deal of the low mortality from pneumonia in the London Temperance Hospital, but the total number treated is too small to provide evidence.

A more accurate method of approaching the problem is to determine carefully the effect of alcohol on normal individuals and those suffering from the acute infections, and if possible the effect on infected animals. With our present means of taking blood-pressure and estimating the systolic output, we are in a position to determine with a fair degree of accuracy the action of alcohol on the cardiovascular apparatus of man.

A limited number of observations of this character have already been made, and although the results are somewhat at variance, as are the results of these same studies on the hearts of the lower animals, these differences can be explained largely by the dosage and the peculiarity of alcohol, that in the same amounts it does not always affect the cardiovascular apparatus in the same manner.

Studies on normal man show that he reacts to alcohol in the same manner as the lower animals. When given in such quantities that the amount in the circulating blood is not greater approximately than 0.15 per cent., or about 6 c.c. of absolute alcohol, little if any effect on the cardiovascular apparatus can be observed. When the quantity given is equivalent to from 0.15 to 0.3 per cent. in the circulating blood, equal to 6 to 12 c.c. of absolute alcohol, there is as a rule evidence of cardiovascular stimulation, as there appears, after a lapse of fifteen to twenty minutes, a moderate rise in blood-pressure, varying from 10 to 20 mm. (Kochmann, Binz, Wiesenfeld). A larger amount, equivalent to 40 c.c. of absolute alcohol, invariably acts as a cardiovascular depressant. Some investigators have been unable to detect a rise in blood-pressure, even with moderate doses (Cabot, Crile). The great difficulty in both animal and man is to determine in any single individual either the minimum or maximum amount required for a stimulating action.

In this respect it differs from other cardiac tonics, as with digitalis, for instance, we may be certain that a given amount will affect the mammalian heart in a characteristic manner. For this reason alcohol must always be an unsatisfactory therapeutic agent, as a remedy which in moderate doses may or may not have the desired effect, and which in somewhat larger doses develops an unfavorable action, is not to be relied on in an emergency.

Regarding the cause of the rise in blood-pressure following moderate doses, Dixon and Kochmann consider it due to constriction of the splanchnic vessels, the associated dilatation of the peripheral vessels failing to compensate for the splanchnic constriction. Wood and Hoyt confirmed this view, as they have shown by means of the plethysmograph that the peripheral vessels were dilated during the rise in blood-pressure, and inasmuch as the pulse-rate was not materially changed it could best be explained by constrictions of the splanchnics. This constriction of the splanchnic vessels, according to Dixon and Kochmann, is due to stimulation of the vasomotor center.

Some work has already been done on the effect of alcohol on the heart of animals suffering from acute infections. Pässler in the course of his extensive experiments on the nature of the cardiovascular disturbance in the acute infections used alcohol, caffein, camphor and digitalis in order to determine their action under these conditions. The effects of alcohol in a few instances were favorable, but in the majority of trials simply increased the vasomotor paresis, which Pässler determined was the most important circulatory disturbance in the acute infections.

The effects of caffein and camphor were uniformly favorable. Dennig,[13] Hindelang and Grünbaum gave infected dogs alcohol by mouth in a dosage equivalent to 6 c.c. of absolute alcohol in man, and noted after five minutes a very transitory rise in pressure, followed by a fall which persisted for forty-five minutes. When larger doses were given equivalent to 20 c.c. of absolute alcohol in man, the primary rise in pressure did *not* develop, but from the beginning the effect was a depressing one.

Carefully conducted studies on the effect of alcohol in the acute infections in man have recently been made by Dennig, Hindelang and Grünbaum.[13] The care with which these observations have been made render them more convincing than the entire mass of conflicting, inaccurate clinical reports.

Patients were selected who were not addicted to the use of alcohol, and the systolic and diastolic blood-pressure and pulse-rate were observed for a period of one or more hours after the administration of the alcohol. This series of studies included sixty-two febrile patients, the majority acute infections. The test was applied to successive groups of patients, each receiving larger amounts of alcohol. The first group of ten, including three pneumonia patients, received, well diluted, an equivalent of 6 to 10 c.c. of absolute alcohol. In all but three cases there was a fall in both systolic and diastolic pressure, and the systolic output, as determined by the product of pulse-pressure by pulse-rate, was reduced. This period of cardiovascular depression continued for one and one-half to two hours.

The second group, consisting of nine patients, including five suffering from pneumonia, received from 11 to 20 c.c. Two pneumonia patients reacted by a slight rise in pressure and increased systolic output; in the remaining seven patients the blood-pressure fell and the systolic output was decreased. The third group, including 25 patients, received, well diluted, an equivalent of 20 to 30 c.c. of absolute alcohol. All but five of these patients gave evidence of the depressing action of the alcohol. Included in the five cases that gave a slight rise in pressure were one pneumonia and one erysipelas. Still larger doses, equivalent to 30 to 40 c.c. of absolute alcohol, were administered to a group of seven febrile patients and all reacted by a fall in pressure and lessened systolic output.

Summarizing this experiment, those patients receiving 6 to 10 c.c., 70 per cent., 10 to 20 c.c., 77 per cent., 20 to 30 c.c., 80 per cent., 30 to 40 c.c., 100 per cent., reacted by a fall in pressure and lessened systolic output. These results on the whole are in accord with those of Cabot, who was unable with varying doses of alcohol to demonstrate in febrile patients a rise in blood-pressure.

---

[13] Dennig, Hindelang and Grünbaum: Deutsch. Arch. f. klin. Med., 1909, xcvi, 153.

The above results, like the animal experiments, impress us with the uncertainty of the reaction of the individual to alcohol; as even in small doses it may, and in large doses invariably does, depress the circulation. It is fair to assume that in these conditions drugs like camphor, caffein and digitalis are of much more value, as they are more constant in their action and much less liable to affect the patient unfavorably.

SUMMARY

In the circulatory disturbances of the acute infections, impairment of the vascular regulating mechanism is more apparent than active disturbance of the heart, and therapeutic measures should be directed toward the prevention or correction of these vasomotor disturbances. Alcohol in man and the lower animals, when taken in small amounts, frequently acts as a cardiovascular stimulant. The exact method of action is still disputed. Larger amounts of alcohol in individuals not addicted to its use, invariably act as a cardiovascular depressant by paralyzing the vasomotor center. The border-line between the amount acting as a stimulant and the amount having a depressing action is variable, and this variability in action renders alcohol an undesirable therapeutic agent.

150 Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. RICHARD CABOT, Boston: In the use of alcohol in these circulatory disorders there is the difficulty of knowing whether one is dealing with alcohol or with a variety of other substances combined with alcohol in the substance known as whisky. When I began to work with alcohol experimentally I tried to use absolute alcohol and it has been said that the use of absolute alcohol in connection with acute disease is advantageous. So far, I have been unable to get any considerable number of patients to take absolute alcohol, either diluted, flavored or in any other way. They objected so strongly that, in my hands, its use has been impractical. Therefore I have had to use that very uncertain mixture known as whisky and all my results in blood-pressure work with whisky have been, therefore, not properely attributable to the action of alcohol. If anyone has found any way in which he can so flavor absolute alcohol to make patients take it without objection I would like very much to hear of it.

DR. A. JACOBI, New York: Alcohol is indicated in cases in which sepsis is imminent. There is no better antiseptic than alcohol, no purer antiseptic. I am satisfied with American whisky; it does my work. There are cases of sepsis from diphtheria, for instance, in which the patients may be saved by whisky. I speak of those cases of diphtheria so malignant from the beginning as not to be touched by antitoxin. In such cases no dose is too large; it is impossible to cause alcoholic intoxication until sepsis has disappeared. Alcohol is not indicated while active hyperemia prevails.

Differential Diagnosis of Chilblains and Lupus Erythematosus.—Chilblains may be confused with lupus erythematosus, which frequently attacks the hands but is seldom confined to that situation; true lupus erythematosus is also very liable to supervene in patients with chilblain circulation, a fact which has originated Hutchinson's term of "chilblain lupus." There is no vesication with lupus erythematosus; it is uncommon in young people who are the chief victims of chilblains; there is no retrogression of the eruption in warm weather, such as takes place in chilblains, and finally there will almost certainly be other patches of lupus erythematosus elsewhere.—E. G. Little, in the *Practitioner.*

MAGNESIUM POISONING

A STUDY OF TEN CASES *

WILLIAM F. BOOS, M.D., PH.D.
Chemist and Pharmacologist, Massachusetts General Hospital
BOSTON

INTRODUCTION

The salts of the Glauber salt group are characterized by the difficulty with which their solutions are absorbed from the gastro-intestinal tract. The most important members of the group are the sulphates of sodium and magnesium.

Both Glauber salt and Epsom salt are easily soluble in water. When these salts are taken into the system in dilute form their solutions pass through both the small and large intestines practically unchanged, because the tendency to absorption is so slight that under these conditions the solutions are virtually non-absorbable and because the salts prevent the absorption of any water which was used to dissolve them. Such solutions passing unchanged through the entire bowel produce their effect in part by simply washing out its contents and partly by their local irritant action on the intestinal wall.

In 1884 Hay[1] showed that the tendency to absorption of Glauber salt is increased by raising the concentration of the solution, and when, in the course of his experiments on animals (the intestinal tract of which was free from fluid) he gave the salt by mouth, he found that large quantities of the dry salt produced no catharsis whatever, while the same doses given in dilute solution invariably produced copious movements. The dry salt was gradually absorbed from the gastro-intestinal tract into the blood and was excreted by the kidneys.

Beginning with concentrated solutions of Glauber salt, Gummilewski[2] found that the addition of water steadily diminished the tendency to absorption. Continuing the dilution, he reached a point below which absorption was reduced to a minimum; from this point on there was practically no absorption down to solutions of 1 per cent. and less. With its slight tendency to absorption the dilute salt solution does not normally remain in the intestine long enough to allow an appreciable amount of the salt to be taken up; if, however, a Glauber salt solution cannot readily leave the bowel on account of mechanical obstruction, or because peristalsis is much diminished or absent, then even a dilute solution will undergo gradual absorption, and there will be no catharsis. In the normal bowel the degree of dilution of an active Glauber salt solution has no bearing on the efficiency of the catharsis produced, a 2 per cent. solution being as effective as a solution containing 5 per cent of the salt, provided, of course, a sufficient quantity of the solution is given in each case.[3]

The question whether or not these salts by their presence in the intestine are capable of abstracting water from the system is still undecided, the experimental evidence on this subject being contradictory. According to Schmiedeberg[4] it is very unlikely that such abstraction tality of pneumonia is largely dependent on the age of the individual, his previous habits, the severity of the epidemic and the stage of the disease in which he comes under observation. Petrescu used his digitalis treatment on recruits—all young and healthy men—in whom the mortality would naturally be low, as Risell by pure symptomatic treatment reported a mortality of only 1.8 per cent. in 127 patients between the ages of 20 and 30 years. Statistics bearing on the value of alcohol in the treatment of acute infections are too few to permit drawing conclusions, even if free from the objections referred to. Dr. John Hay divided a series of pneumonia patients into two lots by assigning every other patient to one group. Those treated without alcohol showed a mortality of 29.5 per cent.; those receiving alcohol 45.5 per cent. We have heard a great deal of the low mortality from pneumonia in the London Temperance Hospital, but the total number treated is too small to provide evidence.

A more accurate method of approaching the problem is to determine carefully the effect of alcohol on normal individuals and those suffering from the acute infections, and if possible the effect on infected animals. With our present means of taking blood-pressure and estimating the systolic output, we are in a position to determine with a fair degree of accuracy the action of alcohol on the cardiovascular apparatus of man.

A limited number of observations of this character have already been made, and although the results are somewhat at variance, as are the results of these same studies on the hearts of the lower animals, these differences can be explained largely by the dosage and the peculiarity of alcohol, that in the same amounts it does not always affect the cardiovascular apparatus in the same manner.

Studies on normal man show that he reacts to alcohol in the same manner as the lower animals. When given in such quantities that the amount in the circulating blood is not greater approximately than 0.15 per cent., or about 6 c.c. of absolute alcohol, little if any effect on the cardiovascular apparatus can be observed. When the quantity given is equivalent to from 0.15 to 0.3 per cent. in the circulating blood, equal to 6 to 12 c.c. of absolute alcohol, there is as a rule evidence of cardiovascular stimulation, as there appears, after a lapse of fifteen to twenty minutes, a moderate rise in blood-pressure, varying from 10 to 20 mm. (Kochmann, Binz, Wiesenfeld). A larger amount, equivalent to 40 c.c. of absolute alcohol, invariably acts as a cardiovascular depressant. Some investigators have been unable to detect a rise in blood-pressure, even with moderate doses (Cabot, Crile). The great difficulty in both animal and man is to determine in any single individual either the minimum or maximum amount required for a stimulating action.

In this respect it differs from other cardiac tonics, as with digitalis, for instance, we may be certain that a given amount will affect the mammalian heart in a characteristic manner. For this reason alcohol must always be an unsatisfactory therapeutic agent, as a remedy which in moderate doses may or may not have the desired effect, and which in somewhat larger doses develops an unfavorable action, is not to be relied on in an emergency.

Regarding the cause of the rise in blood-pressure following moderate doses, Dixon and Kochmann consider it due to constriction of the splanchnic vessels, the associated dilatation of the peripheral vessels failing to compensate for the splanchnic constriction. Wood and Hoyt confirmed this view, as they have shown by means of the plethysmograph that the peripheral vessels were dilated during the rise in blood-pressure, and inasmuch as the pulse-rate was not materially changed it could best be explained by constrictions of the splanchnics. This constriction of the splanchnic vessels, according to Dixon and Kochmann, is due to stimulation of the vasomotor center.

Some work has already been done on the effect of alcohol on the heart of animals suffering from acute infections. Pässler in the course of his extensive experiments on the nature of the cardiovascular disturbance in the acute infections used alcohol, caffein, camphor and digitalis in order to determine their action under these conditions. The effects of alcohol in a few instances were favorable, but in the majority of trials simply increased the vasomotor paresis, which Pässler determined was the most important circulatory disturbance in the acute infections.

The effects of caffein and camphor were uniformly favorable. Dennig,[13] Hindelang and Grünbaum gave infected dogs alcohol by mouth in a dosage equivalent to 6 c.c. of absolute alcohol in man, and noted after five minutes a very transitory rise in pressure, followed by a fall which persisted for forty-five minutes. When larger doses were given equivalent to 20 c.c. of absolute alcohol in man, the primary rise in pressure did not develop, but from the beginning the effect was a depressing one.

Carefully conducted studies on the effect of alcohol in the acute infections in man have recently been made by Dennig, Hindelang and Grünbaum.[13] The care with which these observations have been made render them more convincing than the entire mass of conflicting, inaccurate clinical reports.

Patients were selected who were not addicted to the use of alcohol, and the systolic and diastolic blood-pressure and pulse-rate were observed for a period of one or more hours after the administration of the alcohol. This series of studies included sixty-two febrile patients, the majority acute infections. The test was applied to successive groups of patients, each receiving larger amounts of alcohol. The first group of ten, including three pneumonia patients, received, well diluted, an equivalent of 6 to 10 c.c. of absolute alcohol. In all but three cases there was a fall in both systolic and diastolic pressure, and the systolic output, as determined by the product of pulse-pressure by pulse-rate, was reduced. This period of cardiovascular depression continued for one and one-half to two hours.

The second group, consisting of nine patients, including five suffering from pneumonia, received from 11 to 20 c.c. Two pneumonia patients reacted by a slight rise in pressure and increased systolic output; in the remaining seven patients the blood-pressure fell and the systolic output was decreased. The third group, including 25 patients, received, well diluted, an equivalent of 20 to 30 c.c. of absolute alcohol. All but five of these patients gave evidence of the depressing action of the alcohol. Included in the five cases that gave a slight rise in pressure were one pneumonia and one erysipelas. Still larger doses, equivalent to 30 to 40 c.c. of absolute alcohol, were administered to a group of seven febrile patients and all reacted by a fall in pressure and lessened systolic output.

Summarizing this experiment, those patients receiving 6 to 10 c.c., 70 per cent., 10 to 20 c.c., 77 per cent., 20 to 30 c.c., 80 per cent., 30 to 40 c.c., 100 per cent., reacted by a fall in pressure and lessened systolic output. These results on the whole are in accord with those of Cabot, who was unable with varying doses of alcohol to demonstrate in febrile patients a rise in blood-pressure.

[13] Dennig, Hindelang and Grünbaum: Deutsch. Arch. f. klin. Med., 1909, xcvi, 153.

The above results, like the animal experiments, impress us with the uncertainty of the reaction of the individual to alcohol; as even in small doses it may, and in large doses invariably does, depress the circulation. It is fair to assume that in these conditions drugs like camphor, caffein and digitalis are of much more value, as they are more constant in their action and much less liable to affect the patient unfavorably.

SUMMARY

In the circulatory disturbances of the acute infections, impairment of the vascular regulating mechanism is more apparent than active disturbance of the heart, and therapeutic measures should be directed toward the prevention or correction of these vasomotor disturbances. Alcohol in man and the lower animals, when taken in small amounts, frequently acts as a cardiovascular stimulant. The exact method of action is still disputed. Larger amounts of alcohol in individuals not addicted to its use, invariably act as a cardiovascular depressant by paralyzing the vasomotor center. The border-line between the amount acting as a stimulant and the amount having a depressing action is variable, and this variability in action renders alcohol an undesirable therapeutic agent.

ABSTRACT OF DISCUSSION

DR. RICHARD CABOT, Boston: In the use of alcohol in these circulatory disorders there is the difficulty of knowing whether one is dealing with alcohol or with a variety of other substances combined with alcohol in the substance known as whisky. When I began to work with alcohol experimentally I tried to use absolute alcohol and it has been said that the use of absolute alcohol in connection with acute disease is advantageous. So far, I have been unable to get any considerable number of patients to take absolute alcohol, either diluted, flavored or in any other way. They objected so strongly that, in my hands, its use has been impractical. Therefore I have had to use that very uncertain mixture known as whisky and all my results in blood-pressure work with whisky have been, therefore, not properely attributable to the action of alcohol. If anyone has found any way in which he can so flavor absolute alcohol to make patients take it without objection I would like very much to hear of it.

DR. A. JACOBI, New York: Alcohol is indicated in cases in which sepsis is imminent. There is no better antiseptic than alcohol, no purer antiseptic. I am satisfied with American whisky; it does my work. There are cases of sepsis from diphtheria, for instance, in which the patients may be saved by whisky. I speak of those cases of diphtheria so malignant from the beginning as not to be touched by antitoxin. In such cases no dose is too large; it is impossible to cause alcoholic intoxication until sepsis has disappeared. Alcohol is not indicated while active hyperemia prevails.

Differential Diagnosis of Chilblains and Lupus Erythematosus.—Chilblains may be confused with lupus erythematosus, which frequently attacks the hands but is seldom confined to that situation; true lupus erythematosus is also very liable to supervene in patients with chilblain circulation, a fact which has originated Hutchinson's term of "chilblain lupus." There is no vesication with lupus erythematosus; it is uncommon in young people who are the chief victims of chilblains; there is no retrogression of the eruption in warm weather, such as takes place in chilblains, and finally there will almost certainly be other patches of lupus erythematosus elsewhere.—E. G. Little, in the *Practitioner*.

MAGNESIUM POISONING

A STUDY OF TEN CASES *

WILLIAM F. BOOS, M.D., PH.D.
Chemist and Pharmacologist, Massachusetts General Hospital
BOSTON

INTRODUCTION

The salts of the Glauber salt group are characterized by the difficulty with which their solutions are absorbed from the gastro-intestinal tract. The most important members of the group are the sulphates of sodium and magnesium.

Both Glauber salt and Epsom salt are easily soluble in water. When these salts are taken into the system in dilute form their solutions pass through both the small and large intestines practically unchanged, because the tendency to absorption is so slight that under these conditions the solutions are virtually non-absorbable and because the salts prevent the absorption of any water which was used to dissolve them. Such solutions passing unchanged through the entire bowel produce their effect in part by simply washing out its contents and partly by their local irritant action on the intestinal wall.

In 1884 Hay[1] showed that the tendency to absorption of Glauber salt is increased by raising the concentration of the solution, and when, in the course of his experiments on animals (the intestinal tract of which was free from fluid) he gave the salt by mouth, he found that large quantities of the dry salt produced no catharsis whatever, while the same doses given in dilute solution invariably produced copious movements. The dry salt was gradually absorbed from the gastro-intestinal tract into the blood and was excreted by the kidneys.

Beginning with concentrated solutions of Glauber salt, Gummilewski[2] found that the addition of water steadily diminished the tendency to absorption. Continuing the dilution, he reached a point below which absorption was reduced to a minimum; from this point on there was practically no absorption down to solutions of 1 per cent. and less. With its slight tendency to absorption the dilute salt solution does not normally remain in the intestine long enough to allow an appreciable amount of the salt to be taken up; if, however, a Glauber salt solution cannot readily leave the bowel on account of mechanical obstruction, or because peristalsis is much diminished or absent, then even a dilute solution will undergo gradual absorption, and there will be no catharsis. In the normal bowel the degree of dilution of an active Glauber salt solution has no bearing on the efficiency of the catharsis produced, a 2 per cent. solution being as effective as a solution containing 5 per cent of the salt, provided, of course, a sufficient quantity of the solution is given in each case.[3]

The question whether or not these salts by their presence in the intestine are capable of abstracting water from the system is still undecided, the experimental evidence on this subject being contradictory. According to Schmiedeberg[4] it is very unlikely that such abstraction should take place under normal conditions. If it ever occurs, Schmiedeberg[5] thinks, it will be most likely to happen when the system contains an excessive amount of water, as in cases of general edema, ascites, hydrothorax, pleurisy with effusion, etc. Certain experimental work which I have done on this subject is corroborative of Schmiedeberg's theory. The results of these experiments are to be published in a later paper, together with the results obtained from a quantitative experimental study of the absorption of Epsom salt given in varying concentrations.

The medical literature gives no information concerning the conditions governing the absorption of magnesium sulphate from the gastro-intestinal tract, but the histories in the cases of poisoning by the internal administration of Epsom salt and the results I obtained in my experiments both give evidence to the effect that magnesium sulphate closely resembles sodium sulphate in every particular relating to its behavior after ingestion. Theoretically, therefore, we should expect to find that concentrated solutions of magnesium sulphate are absorbed in part from the stomach and intestines into the circulation, and that when a sufficient amount of magnesium is present in the circulating blood at any one time magnesium poisoning will result.

When magnesium salts are injected into the blood of animals a very characteristic intoxication is produced.[6, 7] The pulse, at first somewhat accelerated, soon becomes slower and slower, until the heart stops in diastole shortly after paralysis of the respiration. The respiration is affected from the start. The reflex irritability is lost twenty minutes after the beginning of the injection and it may still be absent for an hour and a half after respiration has returned to normal. The peripheral motor nerve endings are paralyzed, but where recovery occurs voluntary movements return long before reflex irritability is restored; 0.3 to 0.5 gm. per kilo body weight, given intravenously, produces death in dogs. Subcutaneous application produces qualitatively the same symptoms, but much larger doses are necessary to cause death. On section of the animals Recke[7] found subpleural ecchymoses and extravasation of blood into the pleural cavities.

The work of Meltzer[8] seems to indicate that magnesium salts may produce intoxication through cumulation. I, too, have found the excretion of magnesium sulphate through the kidneys to take place so slowly that if small doses of Epsom salt in concentrated solution are given at short intervals cumulative poisoning may result.

If magnesium absorbed into the blood in sufficient quantity was the cause of intoxication in the cases I shall describe we may expect these cases to show symptoms and autopsy findings resembling those obtained in animals by the intravenous application of magnesium salts.

Of the ten cases which I shall discuss, reports of seven are to be found in the literature; two of the other three cases I have observed personally; the report of the third case I obtained from the records of the Massachusetts General Hospital.

REPORT OF CASES

Case 1.[9]—J. A., 31, Italian, married, second pregnancy, was brought to the hospital on January 22 with a history of having had no movement of the bowels for three days. The patient looked very sick, her respirations were slow and labored, but both the temperature and pulse were only 100. From time to time she vomited yellow watery matter. The uterus, at full term, lay in the right side of the abdomen; it contracted regularly every ten minutes. The left side of the abdomen was puffed up by a distended intestine; there was no visible peristalsis. The examination of a catheter specimen of urine showed the following: Quantity 125 c.c., specific gravity 1,080, no albumin, no sugar. Two glycerin enemas low were given without result. An oil enema gave result from lower bowel. A high turpentine enema gave a good result, relieving the distention. Operation was done for removal of an ovarian cyst. In the urine, which was submitted to me for examination, I found a total of 0.6620 gm. of magnesium, calculated as oxid, and corresponding to 1.95 gm. of magnesium sulphate.

It was impossible in this case to obtain a history of the patient before entrance. Undoubtedly she had been given Epsom salt by her physician, but on account of obstruction of the bowel by the ovarian cyst the salt solution was not permitted to pass out of the intestine; consequently absorption of magnesium sulphate took place. After absorption into the blood the Epsom salt tended to increase the obstipation by paralyzing the bowel.

Case 2.[10]—H. M., 60, chore-man. Diagnosis, chronic bronchitis and emphysema with acute exacerbation; chronic myocarditis.

Patient on entrance passed 30 to 35 ounces of urine, the examination of which gave the following: Odor and color normal, acid, specific gravity, 1,022, albumin, slightest possible trace, sugar absent, no casts. April 14 to 15, the urine rose to 2,940 c.c.; on April 17, it fell to 1,860 c.c., and on April 18 to 480 c.c. On April 14 magnesium sulphate, 1 ounce in concentrated solution every morning was ordered.

April 16, the patient was much more comfortable as a result of rest in bed. He ran an irregular temperature, normal in the morning and up to 101 F., in the afternoon. There were many moist râles and squeaks in the lungs.

April 18 the following information was obtained from Dr. Marks, the junior house officer, and from the nurse in charge of the patient: The patient felt poorly the morning previous. He vomited his salts; his pulse was weak and irregular; he became progressively weaker. His respiration, affected from the start, became more and more labored, and finally resembled Cheyne-Stokes respiration without the periods of apnea. The patient was very cyanotic. His condition seemed so serious that he was placed on the dangerous list.

My attention was called to this case by Dr. Duke, one of the house physicians, who brought me a specimen of urine with a specific gravity of 1,070, and it was in answer to my inquiry regarding the case that I received the above history. I immediately advised the discontinuance of magnesium sulphate for this patient because I was led, from my experience with Case 1, to suspect magnesium sulphate as being the cause of the high specific gravity of the urine. Fortunately the patient had received no salts that morning on account of his weak condition.

April 24 the heart action was less irregular; lungs still showed many coarse râles; temperature still slightly elevated; patient up without ill effects.

The chemical analysis of the 120 c.c. specimen of urine obtained, yielded 0.4813 gm. of magnesium calculated as oxid, and corresponding to 1.42 gm. magnesium sulphate.

In my opinion this case is one of cumulative poisoning produced by a partial absorption of the doses given on

[10] Mass. Gen. Hosp. Rec., 1909, dccxvii, 71.

April 14, 15 and 16. The salt given on April 17 served to hasten the onset of the attack.

CASE 3.[11]—E. I. B., aged 26, milliner, diagnosis, tapeworm. May 23, on entrance to the hospital patient's urine showed a specific gravity of 1,008, albumin, slightest possible trace, no sugar. Patient was put on liquids without milk, and was given 5 grains of calomel that evening.

May 24, the patient was given 7 ounces of Epsom salt, 1 ounce every hour and a half during the morning, with excellent result. No vomiting.

May 25, patient vomited two doses of the salt. There was nausea the rest of the day. Urine, specific gravity 1,029, albumin slightest possible trace. Stool, normal in color, formed, eggs and segments of tenia present.

May 26, patient vomited two doses of salt. She was allowed to rest as quietly as possible, with the hope of beginning treatment.

May 27, patient vomited her medicines; she refused all food and drugs, except teaspoonful doses of albumin water and was beginning to look worn and haggard. She was fed by rectum and given enemas of salt solution. These enemas she retained well.

May 28, all idea of treatment for worm was given up; patient vomited even water. Physical examination was negative except for acne, which appeared two days previously.

May 30, condition of pernicious vomiting continued. Patient was able to retain only teaspoonful doses of milk and lime water or albumin water, and she often vomited these. The vomitus was green and slimy. The patient looked pale and drawn. The pulse was good, the temperature normal. The patient was sleepy most of the time; she lay with eyes closed and hardly seemed to notice what was going on. The nausea was unrelieved. Patient said she could not move her limbs; she thought she was paralyzed. The patient's face was puffy. She was restless and querulous during the night.

The urine was pale, slightly cloudy, specific gravity 1,013, slightest possible trace of albumin casts present. The urine seemed much diminished; patient thought she had not passed any urine for several days, but the nurses thought that she had passed some urine with her stools and when she discharged nutrient enemas.

May 31, at 5 a. m. the pulse suddenly became weak; a few minutes later the house physician found patient pulseless and of a dirty ashen color. The patient was conscious when the heart was merely fluttering. Death occurred at 6 a. m.

Autopsy (M. G. H., Pathological Records, 1906, p. 273; autopsy 1,694).—Pleural cavity contains a slight amount of pale fluid. Peritoneal cavity contains a moderate amount of pale fluid and several pale yellow fibrin clots. Stomach and small intestinal mucosa shows patches of reddening. Kidneys weigh together 320 gm. The epithelium of the cortical tubules is generally flattened, the lumen of the tubules is rather larger than normal. The interstitial tissue is edematous in places. The epithelium of the glomerular capsule is thicker than usual, but there is no evidence of a glomerulo-nephritis, and there is no increase in interstitial tissue. The appearance of the kidney suggests the action of some toxic substance.

This case is undoubtedly one of magnesium poisoning. Unfortunately the urine was not examined for the presence of the salt, but the specific gravity of the urine of May 25 tells the story. At entrance the urine showed a specific gravity of 1,008; on May 25 the specific gravity was 1,029, although the patient had been taking practically no food. On May 31, when nearly all of the salt had been excreted, the specific gravity was 1,013. I have no doubt that specimens with a much higher specific gravity were passed in the twenty-four hours following the voiding of the specimen which was obtained on May 25. This specimen was passed at a time when the excretion of the salt was just beginning. This is another case of cumulative poisoning.

CASE 4.—Under the title, "Epsom Salt as a Poison," C. Fraser[12] reports a most interesting case of magnesium poisoning. A boy, aged 3½ years, took 1½ ounces of magnesium sulphate, mistaking the salt for sugar. On account of the bitter taste he drank a little milk to wash it down. The child's mother found him soon after this, retching and suffering much pain. He complained of great thirst; his bowels had not moved. The nausea and retching continued all day. At 7 p. m. the pain was very severe and vomiting began. The patient suffered great pain all through the night and vomited at frequent intervals. When Dr. Fraser first saw the child at 2:30 p.m. it was twenty-five hours after he had taken the salts. He found the boy in bed with his face pinched, his eyes sunken and the skin very pale. His mind was clear. Every 2 minutes he had a colicky attack which made him draw up his legs. Temperature 100 F., pulse small, 160. Respiration labored. His tongue was very dry, the *papillæ* standing out prominently. His thirst was intense. There had been no movement of the bowels in twenty-four hours. The patient had passed only a half ounce of urine in twenty-four hours. Physical examination showed the abdomen to be distended and rigid, and the skin hyperesthetic. Catheterization yielded ½ ounce of bloody urine, no albumin and no sugar, very acid. The patient was weak and was constantly growing weaker. He vomited every few minutes small amounts of greenish-yellow material without any characteristic odor. The bowels were constipated, temperature and pulse the same.

Next day, vomiting was incessant as before, no movement, no urine, pulse uncountable. The abdomen was so distended and tender that it was feared the boy had peritonitis. He was therefore admitted to the hospital for laparotomy. The child was now in complete collapse, his temperature was subnormal, his pulse 160, the abdomen rigid and retracted. Laparotomy was done and two pints of sterile blood-stained serum obtained from the peritoneal cavity. No cause for intestinal obstruction to be found.

The first twenty-four hours in the hospital the temperature was 100.6 F., pulse 170; child was very ill and restless; he vomited frequently; no flatus or feces were passed in spite of frequent enemas. The child complained of intense thirst. Considerable quantities of blood-stained serum continued to drain from the peritoneal cavity. The dressing was changed every four hours. The child became moribund, and albumin water, brandy and rectal salines were not retained.

The second twenty-four hours the child still seemed moribund; pulse uncountable. Normal saline solution was infused into the subcutaneous tissue of the axilla, after which the child improved, obtaining some sleep. There was still some vomiting, which, however, soon stopped. Half grain of calomel was given every hour. Temperature 101.5 F. In the afternoon flatus and feces passed and again after an enema. Catheterization at 4 p. m. yielded 1 ounce of urine. Recovery now followed quickly.

In this case the action of the salt after absorption into the blood had caused paralysis of the intestine. The slow excretion of the salt was also responsible for the almost complete suppression of the urine, the salt, by its great affinity for water, preventing the excretion of water by the kidneys.

CASE 5.—Neale[13] reports the case of a boy, aged 15, who took 1 ounce of magnesium sulphate in concentrated solution on an empty stomach. The physician arrived after twenty-four hours. In the meantime the boy had had three small movements. A few hours after the dose he felt sick and vomited; this condition continued through the night. The next day he tried to work, but had to give up. The vomiting continued at intervals. When the physician came the patient was lying in an attitude of flexion; he was much cyanosed; from time to time he had severe attacks of tetanic spasms, affecting the right side of the face and the right arm. The urine was dribbling. The pulse was imperceptible. He frequently vomited greenish fluid material. His temperature was 105 F. The next day he was better; 40 ounces of urine were withdrawn by catheter. He was well in a week.

---

[11] Mass. Gen. Hosp. Rec., 1906, dcxl, 122.

[12] Fraser, C: Lancet, London, April 24, 1909, p. 1174.

[13] Neale: Pharm. Jour., 1896, p. 235.

In this case there was evidently a paralysis of the sphincter of the bladder. The tetanic convulsions are an interesting symptom. Two of the ten cases showed convulsions.

Case 6.[14]—A woman in Dundee, Scotland, took 4 ounces of Epsom salt in concentrated solution at one draught. Half an hour later she felt so ill that she sent for a physician. An hour later she died. There was no purging. These are all the facts obtainable in this case, except that death was certified to as due to paralysis from an overdose of salts. There was no inquest.

The cause of death as given in the physician's certificate suggests that there was motor paralysis in this case.

Case 7.—Luff[15] reports the following case: A woman servant aged 20 was found on her bed in the morning. The bed had not been slept in. Death had occurred some hours before. The autopsy was negative except for the presence of a light-colored semifluid mixture of water and magnesium sulphate in the stomach. Death was stated to have been caused by syncope. There was no purging. The salts had been taken on an empty stomach. It was learned later that the young woman had purchased 1 ounce of Epsom salt the day before from a neighboring apothecary.

Case 8.—Sang[16] reports the case of a woman of 35 who took 4 ounces of Epsom salt in warm water to bring on the monthly period. Immediately after taking the salts she felt a burning pain in the stomach and bowels. Her breathing became difficult, she had a choking feeling, also a sensation as if the power were leaving her legs. There was no vomiting and no purging. Her pulse was 98 F.; the pupils were dilated; at times there was slight twitching of the face, but complete paralysis rapidly ensued, the patient became comatose and died seventy-five minutes after taking the salt. The radial pulse was felt for two to three minutes after respiration had ceased. There was no autopsy.

This case is one of the most typical of the ten. It shows the paralysis of respiration in a truly classical manner; also the final complete motor paralysis. Like the third of my cases, the victim in this case spoke of a sensation as if the power were leaving her legs. If Patient 3 had lived longer motor paralysis would probably have developed in her case also. In connection with this case it is interesting to note that Lewin,[17] reporting Case 8 in his text-book on toxicology, expresses his doubt of its being a case of magnesium poisoning because the victim was not purged.

Case 9.[18]—A boy aged 10 was given 2 ounces of Epsom salt for worms. The salt was partly dissolved and partly mixed in a cupful of water. Immediately after swallowing the mixture he staggered and fell. Half an hour later the physician found him breathing slowly and with difficulty. The pulse was imperceptible and the boy was in a condition of collapse. He died in forty minutes. There was no vomiting or purging. The autopsy was negative.

This case is remarkable for the suddenness of the onset, which is strongly suggestive of rapid absorption from the stomach.

Case 10.[19]—An old man who was rather a heavy drinker was the victim of a practical joke. A number of his companions put a large quantity of Epsom salt into his beer. After he had drunk several pints he was suddenly seized with violent purging. He died forty-eight hours later. The autopsy showed the mucous membrane of the gastro-intestinal tract to be inflamed.

The victim in this case may have died in consequence of the violent purging alone.

CONCLUSIONS

In one of these cases only, that reported by Taylor, active purging took place. The victim in this case was given Epsom salt in several pints of beer; the beer served to produce a dilute solution which escaped absorption, and therefore caused powerful catharsis. In Case 3 there is said to have been a good result after the seven doses of Epsom salt, but probably the patient drank with some of her doses of salt an amount of water sufficient to so dilute the salt that it was not absorbed. The patient in Case 4 is reported to have had three small movements. In all the other cases there was no catharsis; the salt, which was taken in concentrated solution, caused paralysis of the bowel after its absorption into the blood. This paralysis was so marked in Cases 1 and 4 that laparotomies were performed.

In all cases there was also a diminution of the urine, which in some cases amounted almost to anuria. The effect on the urinary secretion is due to the presence of the salt in the blood and tissues. On account of its great affinity for water the salt converts a large part of the body fluids into an Epsom salt solution, which, being itself excreted only very slowly, holds the water back and reduces or prevents the secretion of urine.

Among the symptoms observed the paralyzing effect of the salt on the respiration was very prominent; it was spoken of in six cases. Convulsions, described as tonic in character in Neale's case, were seen in Cases 5 and 8. Dilatation of the pupils was observed in Cases 4 and 8. Motor paralysis was seen in Cases 6 and 8, and paralysis of the reflexes seems to have been present in Cases 3 and 8. Vomiting occurred in about one-half the cases.

The most characteristic findings disclosed by operation or autopsy are patches of reddening on the mucosæ of the stomach and intestines and free fluid in the abdominal and pleural cavities (Cases 3, 4, 10).

Fraser's case (4) suggests one very efficient remedial measure, namely, infusion with normal saline solution. The saline infusion given the child undoubtedly saved his life. I think, however, that intravenous application is preferable to intramuscular or subcutaneous infusion, because the relief of the patient will be more prompt and the chances of saving life will be better. The fluid introduced probably acts by diluting the Epsom salt so as to render it less toxic; the more dilute solution is also excreted more rapidly by the kidneys. Meltzer's[20] experiments on animals suggests a specific antagonistic action to magnesium on the part of calcium salts. The intravenous or subcutaneous application of lime salts may therefore be of great value in the tratement of magnesium poisoning.

On account of its paralyzing action on the reflex centers of the cord Meltzer[21] has advised the subcutaneous use of magnesium sulphate in cases of tetanus. Such application should be made with the greatest care only. I can conceive of the remedy being quite as bad as the disease.

SUMMARY

1. Magnesium sulphate in bulk or in concentrated solution is absorbed, in part at least, from the gastro-intestinal tract into the blood.

2. If a sufficient amount of the salt is absorbed at a given time poisoning will result; of the ten cases reported six resulted fatally. The symptoms and autopsy findings in these cases agree very well with those obtained in animals after the intravenous application of magnesium sulphate.

3. On account of the slowness of its excretion from the system, magnesium sulphate, given repeatedly in concentrated solution, may produce poisoning by cumulation.

4. In normal conditions of the bowel magnesium sulphate, in proper dilution, is a valuable cathartic; Hunyadi water, for example, is practically a 3 per cent. solution of Epsom salt (magnesium sulphate 1.5 per cent., sodium sulphate 1.5 per cent.)

5. It is not wise to give magnesium sulphate indiscriminately in cases of so-called acute intestinal obstruction, because when peristalsis is much diminished or absent, and in cases of mechanical obstruction of the bowel, even dilute solutions will be absorbed, with consequent danger of poisoning.

6. In cases of suspected magnesium poisoning large quantities of normal salt solution should be given intravenously. Dilute solutions of lime salts given hypodermically may also be of benefit.

7. The subcutaneous use of magnesium salts to produce catharsis, as proposed by Wade,[22] is not only absolutely irrational, but dangerous.

374 Marlboro Street.

ABSTRACT OF DISCUSSION

Dr. Philip S. Roy, Washington, D. C.: Wolfgang Pauli of Vienna, about 1905, in discussing sulphate of magnesia and some of the other powerful purgatives called attention to their danger. Pauli says that the purgative action of sulphate of magnesia is due to its irritating and caustic action on the tissues, also to a rise in blood pressure. The ion relations of the sulphate of magnesia to protein are similar although not so powerful as those of the bichlorid of mercury. Pauli's article impressed on me forcibly the idea that care should be used in giving the sulphate of magnesia.

Dr. Nathan Rosewater, Cleveland, Ohio: Magnesium citrate is the form of magnesium salt which I give when I wish to produce catharsis. I prescribe it in concentration equivalent to one and one-third ounces of the salt in from four to six ounces of water. In my experience of many years, I have never seen such effects as described by Dr. Boos. It seems to me that one of the cases he reported should be ruled out because the effect was so immediate; absorption can hardly take place so fast as is indicated in his description of the case. In the other cases too I think that the results must have been due to something else than the magnesium, perhaps to the condition for which the drug was given. In only one or two cases do I believe that the Epsom salts seem to have had anything to do with the poisonous results. I have had a large experience with the use of the salts of magnesium and I have never encountered any untoward effects whatever, and have preferred a concentrated solution. It would require more than the report of two cases to make me believe that this agent is a poison, instead of having merely been used in cases with a toxic or fatal ending.

Dr. H. E. Dunlop, Canton, Mo.: It has been my experience, as I am sure it has been of the majority of physicians present, that magnesium sulphate is not at all toxic, at least in the dose usually administered. Does not Dr. Boos believe that idiosyncrasy had much to do with the results reported in his paper?

Dr. D. C. Walt, Little Rock, Ark.: Magnesium sulphate is a valuable agent because of its affinity for carbon which exists in all ptomain bodies. It seems to have the power of neutralizing the toxic value by drawing to its embrace the carbon which is the basic element in poisonous compounds, whether it is the CHNO or CHO group. Nature handles the animal economy on a general plan and that plan is modified or influenced by certain conditions. I dislike to hear anything said against magnesium sulphate because it is one of the most commonly used and cheapest drugs and also one of the most valuable in medicine to-day. With regard to the toxic condition, we must remember that in the snake and in the wasp the toxic effects are based on natural laws, and the toxic effects are regulated by a relation to carbon. I have had a personal experience with this agent as well as in my practice. I have a chronic affection which has been diagnosed as epithelioma, and I have used magnesium sulphate every day for over five years.

Dr. Louis Leroy, Memphis, Tenn.: The report of these cases is extremely interesting and I think they are sufficiently numerous to warrant consideration. What has been stated does not strike me as being a plea to discredit the giving of magnesium sulphate by any means; we must remember, though, that there are certain cases which result unfavorably after the administration of this agent. There seems to be no question but that a solution of magnesium sulphate cannot produce any toxic effects unless the metal in some way unites itself with some other substance. Idiosyncrasy is not usually a question of concentration, but of substance. It seems that it is only when in great concentration that magnesium sulphate is injurious, so that this would seem to argue against idiosyncrasy as being responsible for the unsatisfactory results. On the other hand, I believe that there is very little general toxic action resulting from the administration of magnesium sulphate. The question then arises: Is there not some other toxic material linked with the magnesium and which is absorbed at the same time through the intestines? That would be my interpretation of the cases reported by Dr. Boos. I should say that his cases were the unusual ones; possibly there was an incompletely digested material, or possibly the production of some ptomain substance, which was absorbed and thus caused the poisonous effect. These possibilities must be borne in mind and the report of but one or two instances of supposed poisoning from the administration of sulphate of magnesium should not be accepted as a statement that this is the sole poisonous agent.

Dr. John D. Reid, Pilger, Neb.: I should like to report a case which came to my attention last month, but which was not in my practice. The wife of a blacksmith had not been feeling well for several hours. Thinking that it would do her good, the husband gave her a dose of Epsom salts. Within one hour the woman was dead, whether from magnesium poisoning or not I do not know. Her husband was arrested for murder and the preliminary trial is to be held soon.

Dr. W. H. Philp, St. Francis, Ark.: These reports of deaths from the administration of common, everyday salts are interesting, and recall to my mind the case of a woman who was operated on for a minor gynecologic condition. Two or three days afterward she was given a small dose of salts, not more than 4 drams, and she was dead in one and a half hours, after having just such a set of symptoms as Dr. Boos has described. The case was then recognized as one of magnesium poisoning, but this is the first time it has ever been reported.

Dr. George R. Neff, Farmington, Iowa: I have been using magnesium salts for years, and have never been so successful with them as I have during the last five or six years. I use magnesium internally and externally and expect to use it eternally. I think the sulphate of magnesium is one of the best agents we can use externally for the relief of pain, especially when used with phenol in the proportion of water 16 ounces, salts 1 ounce, phenol 10 drops. In the pleuritic pains in pneumonia, for instance, if this mixture is applied over the chest there are good results. In a knee joint affected with rheumatism, its action is like magic. Think of giving 7 ounces of sulphate of magnesia at one dose! Why should we not get toxic effects from such dosage? It should be remembered that we get toxic effects from medicines, just in proportion as carbon is contained in them. The more carbon the more toxic they are. Epsom salts are eliminative, given in proper doses. Take a case of bronchitis with a continuous hacking cough, and distress; using the following prescription: Epsom salts 3 drams, saccharin 3 grains, tincture of peppermint 10 drops, water 3 ounces, one teaspoonful every hour, the finest results are obtained. It will loosen the dry hacking cough and make a free discharge of mucus and all the symptoms will be relieved. If I had to make a choice of one medicine alone in the whole materia medica to-day, I would choose Epsom salts.

---

[22] Wade: Med. and Surg. Reporter, 1894, No. 4.

Dr. William F. Boos, Boston: I wish it to be distinctly understood that I would not have physicians discontinue the use of magnesium sulphate; I think it is one of the best drugs for the hospital, because it is cheap and efficient in action. But the salt should be given in proper form. Whenever magnesium sulphate is given in greater concentration than 6 or 7 per cent. it is absorbed in part and may produce intoxication. In one case in which the 24-hour urine was examined after the patient had received 1 ounce of magnesium sulphate dissolved in 3 ounces of water (a 33.3 per cent. solution), the urine was found to contain 104 per cent. more magnesium, calculated as oxid, than was normally present. In another instance in which Epsom salt was given in 13.3 per cent. solution, that is, 1 ounce magnesium sulphate in 6 ounces of water, the urine contained 60 per cent. more magnesium than normally. When, however, magnesium sulphate is given in 5 or 6 per cent. solution, that is, ½ ounce magnesium sulphate to 9 ounces of water, there is catharsis and none of the salt appears in the urine.

The last case I reported is probably not one of uremia, because the convulsions in uremia are clonic and not tonic in character. In one case the specific gravity of the 3-ounce specimen was 1,070, it was free from sugar and it contained the equivalent of 1.4 grams of magnesium sulphate. There is no doubt that this was a case of magnesium poisoning and that the high specific gravity was due to the Epsom salt. It is only when we find an excess of magnesium in the urine that we can be certain that the salt was absorbed into the blood and that it was the cause of the intoxication. When the specific gravity of the urine is 1,070 or 1,080, as in the cases reported, or when it is above 1,030 in sugar-free urines generally, this form of intoxication should be thought of. It was only by accident that I found there was such a thing as magnesium poisoning. Magnesium sulphate was injected into the spinal canal by a man in Boston; the patient recovered consciousness about twenty-four hours later. I think it has not been given since. To produce intoxication this agent must circulate in sufficient quantity in the blood. In the cases enumerated, it was absorbed into the blood from the gastrointestinal tract, and the effect is the same as when it is injected intravenously; in both cases we get symptoms typical of magnesium poisoning. Magnesium sulphate should be given well diluted; 1 to 18 is the proper dilution; that is, ½ ounce of the salt dissolved in 3 ounces of water, followed immediately by a glass of water. Such administration will produce prompt catharsis without absorption. In certain hydremic conditions with edema or with fluid in the peritoneal or pleural cavities, even a concentrated solution is not absorbed. I have the records of one autopsy at the Massachusetts General Hospital. The peritoneal and pleural cavities of this patient contained a small amount of fluid and some fibrin clots, the epithelium in the tubules of the kidney was flattened and the interstitial tissue was edematous; there was no evidence of a glomerulo-nephritis, however. The condition of the kidneys suggested action by some toxic material. We do not know how quickly the salt may be absorbed from the stomach, very little being necessary to cause severe symptoms. Idiosyncrasy must always be considered as a possible factor. I do not believe it wise to give magnesium sulphate in cases of intestinal obstruction; in such cases there is a greater tendency to absorption and the longer the salt remains in the bowel the more will be absorbed.

THE DIFFERENT FORMS OF MEDIASTINAL PLEURISY WITH REPORT OF THREE CASES *

ANDERS FRICK, M.D.
Attending Physician Augustana Hospital
CHICAGO

DEFINITION

By mediastinal pleurisy, anatomically speaking, we understand, of course, an inflammation of the part of the parietal pleura which covers the mediastinum, the anterior as well as the posterior. But when we speak of mediastinal pleurisy as a clinical entity we differentiate it as a particular form of pleurisy, not merely because the mediastinal pleura happens to be inflamed, but because in certain clinical aspects it differs radically from ordinary pleurisy. This difference is, however, present only in those cases in which the inflammation of the mediastinal pleura leads to the formation of an encysted gathering of exudate between the mediastinum and the internal surface of the lung. In the following description I shall therefore confine myself to cases of this kind, with exclusion, for instance, of cases in which the inflammation of the mediastinal pleura is a pleuritis sicca, or, if exudative, occurs in conjunction with inflammatory changes in the rest of the pleura with free communication between the different parts of the pleural cavity.

It is owing to the proximity of the mediastinum and its organs that mediastinal pleurisy differs in symptomatology, in diagnosis, and in prognosis from ordinary pleurisy. The characteristic symptoms of mediastinal pleurisy vary, however, according to what part of the mediastinal pleura is involved. A gathering of fluid in front of the right pulmonary peduncle does not give the same symptoms as one in front of the left, and both these forms of mediastinal pleurisy differ in their clinical manifestations from those produced by a gathering of fluid behind the pulmonary peduncle, which, on the other hand, is liable to give the same symptoms, no matter whether it is located on the left or the right side of the posterior mediastinum. We may therefore distinguish between three forms of mediastinal pleurisy: (1) pleuritis mediastinalis anterior sinistra, (2) pleuritis mediastinalis anterior dextra and (3) pleuritis mediastinalis posterior.

It will be my endeavor in this paper to show the justification and the importance of such a distinction.

PLEURITIS MEDIASTINALIS ANTERIOR SINISTRA

Out of the eleven cases reported of left anterior mediastinal pleurisy, seven are described with sufficient detail to give us a comprehensive picture of this form of pleurisy.

Andral's Case 1.[38]—A man of 29, infected with tuberculosis, suddenly had an acute pain between the left breast and sternum with intense anxiety; the countenance was pale, the breathing short and hurried, the pulse hard and frequent. Six days later, a dulness was found between the left breast and the sternum, where respiratory murmur was absent and heart-sounds were weak. The dulness spread over almost the

* Owing to lack of space, this article is abbreviated in The Journal by omission of the historical review and the references to literature. The article appears in full, however, in the Transactions of the Section and in the author's reprints.

entire precordial region and Andral made the diagnosis of effusion in the pericardium. The patient died on the twenty-first day. At the autopsy, the pericardium was found normal, but immediately behind the sternum and the anterior ends of eight or nine left ribs was found a vast cavity formed entirely at the expense of the pleura; it was filled with thick pus and lined with thick false membranes which were studded with numerous tubercles. In discussing this case, Andral points out that there was not much dyspnea, except at the commencement, due to the intense pain, and that death was occasioned not by embarrassment of the respiration, but by the infection, tubercles having been found in most of the internal organs.

Richardière's Case.[9]—A woman had been sick for two months, complaining of constant oppression and attacks of dyspnea. On admission to the hospital, flat percussion-tone was found over the entire left anterior side of the chest with absence of breath-sounds and vocal fremitus and with distant heart-sounds. The oppression grew more intense and she died a month later suddenly. Autopsy revealed a pleuritic abscess containing 700 or 800 gm. of pus, reaching from the middle of the sternum to the left axillary line and completely surrounding the anterior and left side of the pericardium, which was the seat of an intense inflammation.

Pel[10] gives an excellent report of a case:

Pel's Case.—A man of 32 had never been sick until he contracted left-sided pneumonia four weeks before admission to the hospital, Jan. 1, 1884. He complained of pains in the chest and dyspnea. Physical findings were: slight cyanosis, left side of chest bulging and its respiratory excursions diminished, apex-beat not perceivable, a flat tone anteriorly from the clavicle almost down to the costal margin, with absence of breath-sounds and of vocal fremitus; absolute cardiac dulness reaching 1 cm. beyond the right sternal line, heart-sounds distant, clear, and heard best at the right sternal line; posteriorly over almost the entire left side of the chest, flatness and absence of breath-sounds and of vocal fremitus. An incision was made between the eighth and ninth ribs in the left scapulary line and a large amount of pus escaped. The patient improved but slightly, the temperature remained high, he had a chill, the pulse was rapid, irregular, weak, fairly full. A week later, there was a distinct bulging of the precordial region, the apex-beat was not perceptible, the anterior area of flatness extended from the upper margin of the third left rib to 2 cm. beyond the right sternal line and 3 cm. beyond the left mammillary line. The outline of the flat area was triangular; no pericardial rub was heard; and heart-sounds were barely audible. A diagnosis of pericarditis exsudativa purulenta was made. After an incision had been made in the third interspace outside of the parasternal line, about one and a half or two liters of yellow pus came out in a stream which was synchronous with the heart-action. The introduced finger felt the heart beating. The patient improved immediately, but nevertheless, he died three days later of pyemia. The autopsy showed that there was no pericardial effusion, but there were two separate encysted empyemas, one posteriorly which had been opened at the first operation and was in process of healing, and the other on the inner side of the left lung; between the lung and the heart, surrounding the left heart and reaching from the second rib to the diaphragm.

Grancher's Case 1.[11]—An 11-year-old boy, when brought to the hospital, had the classical signs of a large effusion in the left pleura; posteriorly a flatness reaching to the spine of the scapula, with greatly diminished vocal fremitus and with very distant respiration below and bronchial respiration over the middle third of the left lung; anteriorly an area of tympanism below the left clavicle and, below this zone, a flatness which reached downward to the space of Traube, which was only slightly encroached on, and outward to the side of the chest, with diminished vocal fremitus and with bronchial respiration; the heart was displaced toward the right and the maximum of its pulsations was perceived at the right edge of the sternum. Although these symptoms would indicate a pleurisy with free fluid, Grancher made the diagnosis of left anterior mediastinal pleurisy for several reasons. There was no deformity of the thorax, *i. e.*, no enlargement of the left side of the chest, no dilatation of the left costal interspaces, no deviation of the lower end of the sternum toward the left. The maximum dulness was noticed, not behind, but in front and extended 1 cm. beyond the right sternal line, and even on the manubrium sterni the percussion-tone was flat. Furthermore, the displacement of the heart was very exaggerated; there was also a deep cyanosis of the lips and a marked collateral circulation on the chest. Nevertheless, the dyspnea was but slight. As it thus was evident that it was the anterior mediastinum that had yielded to the pressure of the fluid and not the thoracic wall, Grancher concluded that the fluid was not free but encapsulated between the mediastinum and the lung. A puncture was made (Grancher does not mention where it was done) and 850 gm. of serous fluid were withdrawn. The patient recovered.

Grancher's Case 2.[11]—This also concerned a child. The diagnosis of pericarditis with effusion had been made because of an enormous bulging of the precordial region with dulness extending from the sternum to the left side of the chest; the child was almost blue and was in imminent danger of syncope as soon as it was moved in the bed. Grancher considered the dulness too extensive for a pericarditis and found that the heart-sounds were not so obtuse and distant as is usual in pericarditis; they were heard quite well, but with their maximum intensity at the right edge of the sternum. Therefore, without asserting the integrity of the pericardium, Grancher concluded that probably mediastinal pleurisy was present. Puncture was made in the left axillary line and 950 gm. of serous fluid were withdrawn. The heart came back to its normal position, the dyspnea disappeared in a few hours, and the child recovered.

Thoinot and Griffon's Case.[13]—These authors have given an incomplete report of the case of a 45-year-old woman who was brought to the hospital on the fifth day of her disease, with the typical history of a pleuropneumonia of the left side. She suffered intensely from pain and dyspnea. Her countenance was pale and she was evidently deeply infected. There was distant bronchial respiration, Traube's space was sonorous, and the heart was hardly displaced. She died on the seventh day of her illness. At the autopsy a small collection of pus was found between the left lung and the anterior mediastinum; there were thick fibrinous membranes; the lower left lobe was consolidated. Pneumococci were found in the pus.

Dodd's Case.[15]—This was one of a 57-year-old man who about a month before had had pneumonia of the left lower lobe and thereafter had developed the usual symptoms of empyema. Percussion in the front gave dulness from the third left rib downward and from the edge of the sternum to the mammillary line, with absence of respiratory sounds; the apex-beat was closer to the sternum than normally; there was a place of tenderness as large as the end of a finger at the junction of the fifth rib and the sternum. Behind, there were dulness and absence of respiration-sounds from the seventh rib downward. Resection of the eighth rib was made in the midaxillary line and 250 c.c. of pus was evacuated. The patient improved only temporarily, the left lung gradually expanded, and vesicular breathing was heard to the base of the lung. But anteriorly, the only change to be found was that the apex-beat had returned to within half an inch of its normal position. He died twelve days after the operation from embolism in the left side of the brain. At the autopsy, an abscess with 300 c.c. of pus was found between the pericardium and the left lung and was in relation with the anterior wall of the chest only in the fourth intercostal space from the mammillary line for about 3 cm. toward the sternum. A needle in the fourth interspace, 1 cm. inside the mammillary line, would probably have found the abscess without entering the pericardium.

From the reports of these cases we find that the left anterior mediastinal pleurisy corresponds closely to ordinary exudative pleurisy in regard to etiology and pathology and to general symptoms, *i. e.*, those due to the infection. It is usually caused by the tubercle bacillus or the pneumococcus; the exudate is either serous or purulent, the latter being accompanied with formation of pseudomembranes. It is rare to find cases of left anterior mediastinal pleurisy without complications. Tuberculosis of other organs, a pericarditis, an empyema of another part of the left pleura, a pneumonia of the left lower lobe, an embolus of the brain are the complications which have been recorded in the reports of these cases.

The left anterior mediastinal pleurisy owes its distinctive features, of course, to the localization of the pathologic process. In some cases the entire height of the left anterior mediastinal pleura is affected; in other cases the pathologic changes are confined to the lower part of it. There is no case on record in which the inflammation has spread above or below the pulmonary peduncle to the posterior mediastinal pleura, but in some cases the anterior median parts of the left diaphragmatic and parietal pleuræ have also been involved. At times the larger part of the exudate is covered by the anterior edge of the left lung, leaving only a small part of it in relation to the thoracic wall, underneath and close to the sternum, but usually, if the effusion is somewhat large, and particularly in case of a serous exudate, the edge of the lung is displaced more or less outward, exposing a larger part of the exudate.

Of the subjective symptoms the pain is the most characteristic one, being localized behind the sternum or between the sternum and the left breast; it varies greatly in intensity and is not always present. The degree of dyspnea, of oppression, of anxiety, seems to be more proportionate to the severity of the pain than to the amount of exudate. Thoinot and Griffon's patient suffered intensely from pain and dyspnea, although the amount of pus was small, while in Grancher's first case the dyspnea was very moderate, although the effusion measured nearly 1,000 c.c

The objective phenomena vary, of course, according to the size of the effusion. A small effusion will cause an area of flatness extending only from the left sternal line to the left nipple-line, with diminished or absent vocal fremitus and respiration-sounds over the flat area, with only slight or no displacement of the heart, and with no cyanosis. If the effusion is large, it may cause a bulging of the precordial region and the flat area may reach from several centimeters beyond the right sternal line to the left axillary line and upward to the second rib, and we may find a flat percussion-tone even over the manubrium sterni. In these cases the anterior mediastinum is more or less displaced to the right; the apex-beat may be seen close to the sternum, but is usually not perceivable; in several cases the heart-beat has been noticed at the right sternal line. As a consequence of the displacement of the heart, more or less deep cyanosis may appear, but it seems to be of rare occurrence; only in one case was an engorgement of the thoracic veins noticed, the disturbance of the circulation being due probably to interference in the right auricle and the superior vena cava. To explain the cyanosis in cases of left-sided pleuritic effusion, as some authors do (Moxon[37]), as a result of pressure on the left auricle with subsequent stasis backward and dilatation of the right heart, seems scarcely to be accurate, as only the auricular appendage is covered by the left mediastinal pleura, and consequently liable to be exposed to pressure, while the rest of the left auricle is in relation to the organs contained in the posterior mediastinum. The respiration-sounds and vocal fremitus over the dull area are, as usually in pleurisy with effusion, diminished or absent. The heart-sounds are obtuse and distant and more clearly heard at right sternal line than to the left of the sternum.

The prognosis in left anterior mediastinal pleurisy is more serious than in pleurisy with free exudate because of the greater pressure to which the heart is exposed, and perhaps also because of greater danger of a complicating pericarditis or cerebral embolus.

In regard to the diagnosis of left anterior pleurisy, the main difficulty is to differentiate it from an exudative pericarditis, from a pleurisy with free exudate, and from an anterior suppurative mediastinitis.

The differential diagnosis between exudative pericarditis and left anterior mediastinal pleurisy is no doubt difficult. "Handelt es sich doch hier," as Pel says, "um die Unterscheidung einer Pericarditis suppurativa interna von einer Pericarditis suppurativa externa." We find in both a precordial dulness or even bulging, an apex-beat located inside the left border of the dull area, or entirely absent, distant heart-sounds; the triangular shape of the dull area usual in pericarditis has been observed also in a case of left anterior mediastinal pleurisy; cyanosis occurs in both; the character of the pulse is of no assistance in making a diagnosis. There is, however, one sign which if present is characteristic for left anterior mediastinal pleurisy, as Grancher has already pointed out, namely, that the heart-beat is perceived with its maximum intensity and the heart-sounds are heard most distinctly near the right sternal edge. It indicates that the heart has been pushed toward the right by a pleuritic effusion and not removed from the proximity of the anterior chest wall by the interposition of a pericarditic exudate. Other signs may be of help for the diagnosis. A well-marked border-line between the flat area and the resonant area over the left lung speaks in favor of a pericarditis. The presence of Skoda's sign below the left clavicle, or of signs of congestion or of inflammation of the left lower lobe, or of signs of another encysted pleuritic effusion speak in favor of a mediastinal pleurisy.

Left anterior mediastinal pleurisy might be mistaken for a pleurisy with free exudate under two conditions. One of them is that, in addition to the left anterior mediastinal pleurisy, another encysted gathering of fluid exists in the lower posterior part of the left pleura; a puncture will then be made posteriorly and the fluid withdrawn, but the symptoms from the anterior part of the chest will remain unchanged and a correct diagnosis will be possible. The other condition is that, in a case of left anterior mediastinal pleurisy, the left lower lobe is congested and surrounded by a thin layer of fluid, as occurred in one of Grancher's cases; a correct diagnosis was here made, when by careful observation, admirable for its accuracy, it was demonstrated that it was the mediastinum and not the thoracic wall that had yielded to pressure from the fluid.

The differentiation of left anterior mediastinal pleurisy from anterior suppurative mediastinitis (Hare,[30] Christian[38]) also offers some difficulties, at least under certain conditions. When a mediastinitis is due to a trauma or to a sternal osteomyelitis or to a mediastinal lymphadenitis, the diagnosis might be quite clear; but, when, as occurs in rare cases, it is caused, through extension of the inflammatory process, by a pulmonary affection or by a pleurisy or a pericarditis, it seems hardly possible to arrive at a definite diagnosis.

A skiagram might be of service for diagnosing this kind of cases, but no mention is made of its use in any of the reports which have been published hitherto.

PLEURITIS MEDIASTINALIS ANTERIOR DEXTRA

While no reports of right anterior mediastinal pleurisy could be found in the literature, two cases of this kind have come under my notice.

Case 1 (personal).—Adolph N., a tuberculous subject, aged 37, on June 12, 1906, suddenly became very sick, had a severe chill and a very acute pain which he located in the right side of the chest, especially between the sternum and the right nipple, and which made it extremely difficult for him to breathe. He was admitted to the Augustana Hospital June 18, 1906. Temperature 102, pulse 86 and respiration 24. His lips were dark blue; both head, neck, thorax and upper extremities were deeply cyanotic, and the veins in these regions were engorged. Amphoric breathing and large crackling râles were heard below the right clavicle. The percussion-tone was dull over the lower anterior part of the right lung, with distant breath-sounds of vesicular character and only faintly perceptible vocal fremitus. Over the posterior part of the right lung, there was normal resonance and vesicular breathing. A dulness over the corpus sterni I ascribed to a dilatation of the right heart. Over the lower anterior and lateral part of the left lung, there were signs of a small effusion, probably remaining from an attack of pleurisy he had had a year previously. The apex-beat could not be located.

During the following three weeks, I tried in vain to determine the locality of the effusion, of the presence of which I had no doubt. I made numerous punctures over the lower anterior part of the right lung, all with negative results. A consulting physician was called, but could find no evidence of a gathering of fluid. In the meantime the patient suffered agonies, was deeply cyanotic, was practically gasping for breath both night and day, had an extremely severe pain in his chest, which made frequent hypodermic injections of morphin necessary. He could not eat on account of the dyspnea. The temperature usually remained at about 98 or 99, but occasionally rose to 101 F.; the pulse was not very rapid, varying between 73 and 100 a minute; the respiration varied between 16 and 28 a minute.

Finally on July 13, finding a very narrow margin of flatness and total absence of breath-sounds and vibrations along the right edge of the sternum, I introduced the exploratory needle in the fourth right interspace about 1 cm. from the sternum and aspirated a syringeful of serous fluid. Dr. A. J. Ochsner was asked to operate, partly because I did not like to introduce a large aspirating needle where I had made the exploratory puncture, on account of the proximity of the heart, and partly because I considered a continuous drainage necessary to relieve the condition permanently. The operation was performed the same day. After the sternal end of the fifth rib had been resected and the pleura had been incised, the lower anterior corner of the lung was seen in the wound and was seemingly normal. A finger was introduced around the anterior edge of the lung and as soon as it was pushed down between the lung and the mediastinum, there was a gush of serous fluid, the amount of which was estimated at about 500 c.c.

After the operation the cyanosis rapidly disappeared and the dyspnea was greatly relieved. Unfortunately, however, the patient was so exhausted that he failed to pick up and died July 20, 1906, a week after the operation. Autopsy was not permitted.

Case 2 (personal).—George G., aged 30, a laborer, was admitted to the Augustana Hospital March 18, 1908. He had been well up to March 15, when he suddenly became sick. On admission he complained of a moderate pain in the right side of the chest, coughed, but expectorated only some frothy mucus; at no time did he raise any typically pneumonic sputum. He had to sit up in bed to get air, and evidently suffered greatly from dyspnea. Temperature 103.3, pulse 156 and respiration 48. His lips were dark blue; both head, neck and upper extremities were deeply cyanotic, and the veins in the cyanosed parts were engorged. The apex-beat was seen two finger's breadth outside the left nipple-line; a dulness over the corpus sterni I ascribed to a dilated right heart; the heart-tones were clear. The left lung was normal except that the respiration-sounds were increased. Over the entire front part of the right lung there was marked dulness, increasing downward, and also over the lower half posteriorly; the upper posterior half was resonant. The vocal fremitus was increased over the upper part anteriorly, slightly diminished below. Bronchial breathing was heard over the entire front part of the right lung, close to the ear over the upper part, and more distant over the lower.

On March 19 venesection on right arm was made, as it was thought possible that the cyanosis was due to dilatation and insufficiency of the right heart. A quantity of dark blood (300 c.c.) was removed; no improvement. March 20 an exploratory puncture was made in the fifth interspace, just outside the right mammillary line, also with negative result. The next day I made a second puncture in the same interspace, but inside the mammillary line, also with negative result.

March 23, his condition was practically unchanged, the dyspnea was very severe, the cyanosis deep and the pulse was at times irregular. On examination I found a small area close to the right sternal edge where the dulness was particularly marked, the breath-sounds were barely audible, and the vocal fremitus was totally absent. I had observed the same phenomena on the day of his admission, but explained it as being due to a dilatation of the right heart. As, however, no other signs of such a dilatation were observed, I became convinced that an effusion between the right lung and the mediastinum was causing both the displacement of the apex-beat and the cyanosis as well as flatness and absence of both fremitus and breath-sounds. The exploratory needle was therefore introduced for the third time, but now in the fourth interspace, between the parasternal line and the sternal edge. A turbid, yellowish fluid was obtained. The same day the patient was operated on by Dr. E. H. Ochsner. The sternal end of the fifth rib was resected and about 500 c.c. of fluid removed. The cyanosis soon disappeared after the operation and the dyspnea was gradually relieved. The draining fluid gradually turned into thick yellow pus, the wound granulated and healed, and on June 8, 1908, the patient was discharged after having made an uninterrupted recovery. I regret to say that no effort was made to ascertain what micro-organism was the cause of the pleurisy. I believe, however, that I am justified in saying that it probably was a case of primary pneumococcus-infection of the pleura with secondary or simultaneous congestion of the lung.

From the reports of these two cases of right anterior mediastinal pleurisy, it will be seen that they, in many respects, showed a similarity with cases of left anterior mediastinal pleurisy. They were caused, one by tuberculosis, one by pneumococcus infection. In one of them the exudate was serous, in the other purulent. Most of the symptoms were like those caused by left-sided pleurisy: pain, most severe between sternum and right breast, dyspnea and oppression in proportion to the pain, a flatness along the right sternal edge and over the corpus sterni, a dulness over a smaller or larger part of the right lung, due to simultaneous congestion, absence of breath-sounds and vocal fremitus over a narrow flat area close to the sternum, and displacement of the heart.

In but one respect, I believe, the two cases of right anterior mediastinal pleurisy differed materially from those on the left side, namely, in regard to cyanosis, and this difference is sufficiently great, in my opinion, to form one of the reasons why the right and the left anterior mediastinal pleurisy should be distinguished as two different forms. In the two cases observed by me, the most striking feature was the cyanosis, which was extremely deep. Furthermore, the cyanosis was limited to head, neck, thorax and upper extremities and the veins in these regions were engorged. In Andral's and Thoinot's cases of left anterior mediastinal pleurisy, the countenance was pale; in Pel's case there was slight cyanosis; in Richardière's and in Dodd's cases no mention was made of the complexion and consequently one is justified in assuming that, if cyanosis was present, it was not marked. Only in Grancher's two cases was the cyanosis deep, and only in one of these were the thoracic veins dilated. Both patients were children with very large effusions.

It is only natural that cyanosis should be an early symptom in right anterior mediastinal pleurisy, when one considers that it is the right auricle and particularly its upper extension, the superior vena cava with its easily depressible walls, that are directly covered by the right mediastinal pleura, and are the very first organs that will be exposed to pressure from an effusion gathering between the right lung and the anterior mediastinum. The intrathoracic part of the inferior vena cava seems to be too short and located too far backward to suffer from pressure from the exudate; at least in my two cases there were no signs of passive congestion below the thorax. On the left side conditions are somewhat different. An effusion gathering between the left lung and the anterior mediastinum will cause pressure on the right and left ventricles; but as their walls are rigid, no disturbance of the circulation will arise until the effusion becomes large enough to displace the heart considerably toward the right and thus cause, secondarily as it were, a pressure on the right auricle and the superior vena cava.

Another reason, however, for differentiating the right and the left anterior mediastinal pleurisy as two distinct forms, is the difference in their differential diagnosis. While either of them could be mistaken for a pleurisy with free exudate or a suppurative anterior mediastinitis, it is only a left anterior mediastinal pleurisy that could be confounded with pericarditis and only a right anterior mediastinal pleurisy that could be confounded with a dilated right heart and with any disease causing a direct pressure on the commencement of the superior vena cava.

Right anterior mediastinal pleurisy and dilatation of the right heart both produce dulness over the sternum extending beyond the right sternal edge, displacement of the apex-beat toward the left, and cyanosis. It should not, however, be difficult to differentiate these two conditions because, when these three symptoms, dulness, displacement of apex-beat, and cyanosis are as pronounced as they were in the two reported cases and if they are due to dilatation of the right heart, other symptoms of dilatation must necessarily also be present, namely, epigastric pulsations, tricuspid murmur, and venous pulse, symptoms which are not found in right anterior mediastinal pleurisy.

Any pathologic formation causing pressure on the superior vena cava may give symptoms similar to those of the right anterior mediastinal pleurisy; but particularly mediastinal sarcoma and carcinoma, aneurism of the aorta, and anterior suppurative mediastinitis should be differentiated from this form of pleurisy. The history of the disease, its mode of onset, as well as its course, the presence or absence of signs of infection, among which a high leukocytosis is of special importance, the presence of coordinate symptoms, are factors which, when carefully considered, should be sufficient to insure a correct diagnosis. The possibility of other mediastinal tumors or inflammatory products being present (Hare[30]) should be kept in mind, as a lymphadenitis, a mediastinal dermoid cyst, a syphilitic mediastinal gumma (Buttino[40]), a lipoma, a metastatic cancer, an endothelioma, a branchioma (Duret[41]), a chrondroma, a fibroma, hematoma, a fibrous infiltration, enlargement of mediastinal glands or of thymus, etc.

PLEURITIS MEDIASTINALIS POSTERIOR

Eleven cases of posterior mediastinal pleurisy have been previously reported.

Andral's Case 2 (Cited from Dieulafoy[16]).—A 37-year-old man entered the hospital June 14, 1822, showing signs of pulmonary phthisis in the last stage. June 17 he had a vomica, expectorating a large amount of pus. He died July 8, 1822. At the autopsy, numerous tuberculous cavities were found in both lungs. There was a perforation the size of a pea of the posterior part of the right main bronchus, leading into a cavity which was large enough to admit an orange. This cavity was bounded exteriorly by the right lung, posteriorly by the ribs, interiorly by the spinal column and the posterior mediastinum, anteriorly by the right pulmonary vessels.

Dieulafoy's Case 1.[17]—A 44-year-old woman caught a cold and had chills; next day she began to have a cough, which soon became paroxysmal and she was considered to have whooping-cough. After two months she became hoarse, a few days later stridor appeared, and she had violent attacks of suffocative cough, which was accompanied, if coming on shortly after a meal, by vomiting, and followed by the expectoration of a whitish, frothy suptum. Finally it became difficult for her to swallow. She entered the hospital three months after the beginning of her illness. On examination, no abnormal signs from the chest were found, the temperature was normal, but the larynx and the trachea deviated toward the right, the false vocal cords were edematous, there was *no* paralysis of the recurrent nerve. She gradually grew worse, the stridor became still more pronounced, the dyspnea was continuous. A week after her admission, she had a chill, followed by fever, and a few days later she had a vomica and expelled, during twelve hours, 200 gm. of yellow pus, which contained pneumococci. The diagnosis of posterior left mediastinal pleurisy was made. The symptoms gradually disappeared and the patient recovered.

Dieulafoy's Case 2.[17]—A young, healthy man suddenly became sick with chills, oppression and dyspnea, which at first came on only on exertion, but soon became permanent and was aggravated by the slightest effort. A few days later he began to have fits of paroxysmal, dry cough, resembling whooping-cough, and at the same time his voice became husky. Four weeks later, deglutition became difficult and only liquids could be swallowed. Five weeks after the beginning of his illness, he was admitted to the hospital. A loud *inspiratory stridor* was heard, there was depression of jugulum and epigastrium at each inspiration, the veins of the upper part of the chest were dilated. At the level of the third and fourth vertebræ a small area of dulness was found between the scapula and the spine on the left side, over which area bronchial respiration and a few râles were heard. On the day after his admission he had a vomica and expectorated about 80 gm. of thick greenish pus. No bacteria were found, but the patient's blood-serum agglutinated pneumococci. He gradually recovered completely.

Breton's Case.[19]—A 47-year-old laborer, an alcoholic, in May, 1904, began to complain of palpitations and dyspnea on exertion, and shortly afterward of severe retrosternal pains and precordial angina with sensation of faintness and with vertigo. On his admission to the hospital in June, 1904, he was intensely anemic, had no fever, remained in dorsal position, in which his respiration was free, while any other position caused oppression and dyspnea. Physical examination of the lungs revealed only a slight dulness close to the spine on the left side. The apex-beat was seen 1.5 cm. outside the nipple line, palpation gave the impression of violent cardiac contractions. The closure of the aortic valves was accentuated and was heard also to the right of the spinal column; the pulsations in the crural arteries were asynchronous. Gradually a dulness in the aortic region appeared, slowly increasing and spreading along the right sternal edge, and, at about the same time, a murmur could be heard in the third right interspace which at first was single, systolic, soft, and afterward became double. Radioscopy showed a dark zone close to the left lateral aspect of the spinal column at the level of the mediastinum. The patient began to have a slight cough, but still no fever. The diagnosis of aneurism of the thoracic aorta was made. The patient gradually grew worse and in July, 1904, new symptoms appeared: cachectic discoloration of the skin, dilatation of the thoracic veins, hoarseness and dysphagia. The diagnosis of aneurism was abandoned for one of neoplasm of the posterior mediastinum. The patient died August 1, 1904, in extreme dyspnea. Three days previous to death the temperature was febrile.

At the autopsy a pleural abscess containing 300 or 400 gm. of yellow pus was found between the posterior mediastinum and the left lung, closely adherent to the descending aorta. The adjacent pulmonary parenchyma showed traces of subacute inflammation. The pericardium contained 200 gm. of serous fluid, the myocardium was hypertrophic, no valvular lesions were found and the aorta was normal, excepting a thickening of its membranes where it adhered to the abscess. Amyloid degeneration was found in the liver and kidneys.

AUTHOR'S CASE.—One case of posterior mediastinal pleurisy has come under my personal observation. Nils L., aged 35, a teamster, contracted pneumonia in April, 1897. After five days he began to improve, but after another week or two he gradually became worse again, had severe chills at irregular intervals, expectorated yellow pus, usually only small amounts, but a few times by the mouthful, in fact, so much that it came out both by nose and by mouth; he was losing in weight and the feet began to swell. When this condition had lasted about two months, I was called to see him. He was then emaciated, temperature 102, pulse 92, respiration 22 to the minute; he complained of slight dyspnea, but could breathe comfortably when in bed. There was dulness over the entire left lower lobe posteriorly, bronchial respiration was heard over the lower part of the scapula and the breath sounds were faint and distant over the inner and lower parts of the left lung posteriorly. The urine contained a small amount of albumin and there was a considerable swelling of the feet (beginning amyloid degeneration of the kidneys). A few days later, on closer examination, I found a narrow vertical zone parallel with and close to the spine, where the percussion tone was flat and where breath sounds and vocal fremitus were absent. An exploratory puncture was made in the seventh costal interspace, fairly close to the spinal column; yellow pus was obtained, which contained numerous pneumococci. The next day, after the patient had been anesthetized, two more exploratory punctures were made, more laterally and lower down than the first one, as it was thought advantageous, in order to insure free drainage, to have the opening laid as low as possible, but when the result was negative in both instances, a resection of the eighth rib was made, close to the spine and about 250 c.c. of pus emptied out of the encapsuled cavity. The wound gradually closed, the patient recovered and gained 50 pounds in weight in less than half a year. No symptoms of pressure on the mediastinum and its organs were present in this case.

OTHER CASES.—Chauffard[18] reported four cases of posterior mediastinal pleurisy with serous effusion. In none of them were there any pressure symptoms. The diagnosis was based on the presence of a narrow, vertical dulness along the spine, with the usual symptoms of effusion. Exploratory puncture was made in three of them with positive results. All of the patients recovered spontaneously.

Fernet[20] reported two cases of posterior mediastinal pleurisy, both on the left side, one following after pneumonia and one after lung gangrene. Both cases showed the general symptoms indicating the presence of a collection of pus, and this was located when an area of flat percussion tone and absence of vocal fremitus was found between the inner edge of the scapula and the spine. In both cases the third and fourth ribs were resected close to the spinal column and a large amount of pus removed. In one of the cases the patient had a vomica of about 50 gm. of pus a few days after the operation. No symptoms of pressure on the posterior mediastinum were present in either of these two cases and it seems that although it was chiefly the mediastinal pleura that was affected, the inflammation also involved the pleural covering of the interlobar fissure and of the diaphragm.

Laffoigue's case,[21] of which only an incomplete report is given, concerned a 22 year old man who, when admitted, had high fever, did not cough and had no dyspnea. A week later the apex beat was found two fingers' breadths outside the mammillary line, and another week later, signs of effusion (dulness, egophony, bronchial expiration) were noticed over a longitudinal area to the right of the spinal column. A skiagram confirmed the diagnosis, but exploratory puncture gave a negative result. The patient gradually recovered, the dulness, etc., disappeared spontaneously and the apex beat receded to its normal position. The author considered that both the anterior and posterior mediastinal pleura were affected in this case. In view of the fact, however, that exploratory puncture between the spine and the scapula was negative, one may be justified in doubting the correctness of the diagnosis.

Out of these twelve cases nine are of only moderate interest, as they give no symptoms of pressure on the posterior mediastinum. They were ordinary cases of partial, encysted pleurisy with a somewhat unusual localization between the lung and the posterior mediastinum. In their symptomatology and diagnosis they differed in no respect from an ordinary encysted pleurisy and their distinction as a special form would hardly be warranted if an encysted pleuritic exudate of the same localization were not liable, under other circumstances, by pressure on the posterior mediastinum and its organs, to produce symptoms which are radically different from the usual ones of pleurisy as exemplified by Breton's one and Dieulafoy's two cases. The reason why an encysted exudate between the lung and the posterior mediastinum does not, in all cases, produce pressure-symptoms is not quite clear. The amount of the exudate is evidently of only partial importance, as in one of Fernet's cases two liters of pus gave no pressure-symptoms, while in Breton's case only three or four hundred grams of pus produced very serious ones. Probably the occurrence of pressure-symptoms is dependent on how early the adhesions are formed and how deeply the exudate is situated. In both Dieulafoy's and Breton's cases the abscess was evidently remote from the surface, as the only superficial finding was a slight dulness between the scapula and the spine.

The posterior mediastinal pleurisy corresponds, just as does the anterior mediastinal form, to ordinary exudative pleurisy in regard to etiology, pathology, and general symptoms and gives a distinctive clinical picture only when it produces pressure-symptoms on the organs contained in the posterior mediastinum.

In Dieulafoy's Case 1 the exudate caused paroxysmal cough by pressure on the left pneumogastric nerve, stridulous inspiratory dyspnea, edema of larynx and hoarseness by pressure on the trachea, which deviated toward the right, and, perhaps on the recurrent laryngeal nerve, and, finally, dysphagia by pressure on the esophagus.

In Dieulafoy's Case 2 the exudate caused paroxysmal cough by pressure on the left pneumogastric nerve, stridulous inspiratory dyspnea with depression of jugulum and epigastrium by pressure on the trachea, dysphagia by pressure on the esophagus, and engorgement of the thoracic veins by pressure on the left azygos veins.

In Breton's case the exudate seems to have exerted pressure almost exclusively on the thoracic aorta, resulting in retrosternal pain and precordial angina, palpitations, dyspnea on exertion, accentuated closure of the aortic valves, and hypertrophy of the left ventricle with the apex-beat displaced toward the left.

Posterior mediastinal pleurisy is always unilateral. In six of the twelve reported cases, the left posterior mediastinal pleura was affected, and in five of these the exudate was purulent, in one putrid; the right posterior mediastinal pleura was affected in six cases, and in all of these cases but one was the exudate serous.

The prognosis of posterior mediastinal pleurisy seems to be very much less serious than of the anterior, as, out of the twelve cases, only two ended fatally. In this connection it may be worthy of note that, out of the seven cases with purulent or putrid exudate, vomica occurred in not less than five, and that in two of these five cases thoracotomy was not found necessary, as the abscess gradually emptied itself completely through the air passages.

The diagnosis of posterior mediastinal pleurisy, in cases in which no symptoms of pressure on the posterior mediastinum are present, is based on the same principles as the one of any encysted pleuritic effusion. When symptoms of pressure arise, a differential diagnosis must be made between posterior mediastinal pleurisy and any disease which is liable to produce pressure.

I shall confine myself to the enumeration of such diseases: (1) abscess of the posterior mediastinum, whether due to trauma, foreign body, suppuration of glands, perforation of esophagus or trachea, or to an inflammation spreading from an adjacent organ as, a retropharyngeal abscess, a pulmonary abscess, a suppurative pericarditis, a vertebral osteitis, or to metastasis; furthermore, (2) hypertrophic glands, (3) aneurism, (4) gumma, (5) *neoplasm.*

In case stridor is present, a differentiation should be made, as Dieulafoy points out, from any tracheal lesion, whether intrinsic or extrinsic, which is liable to produce stridulous dyspnea, as intratracheal gumma, polyp, stenosis, pressure from cervical glands or from struma.

TREATMENT

The treatment of mediastinal pleurisy, whether anterior or posterior, differs in no way from the usual one of any encysted pleurisy except that the indication for surgical interference comes earlier than in any other form. In order to be able to make a thoracocentesis or a thoracotomy at the proper moment, we should not hesitate to make not only one, but if necessary, several exploratory punctures to locate the exudate. No rule can be given as to where to introduce the exploratory needle. By minute physical examination we should try to determine where the maximum flatness is located, where the vocal fremitus is least perceptible, where the breath-sounds are most distant, where egophony is most pronounced, and introduce the needle in the outer edge of the area thus determined.

CONCLUSIONS

1. The clinical manifestations of mediastinal exudative pleurisy differ according to the part of the mediastinal pleura involved, and consequently according to the part of the mediastinum exposed to pressure.

2. For this reason three different forms of mediastinal pleurisy are to be distinguished: (1) pleuritis mediastinalis anterior sinistra, (2) pleuritis mediastinalis anterior dextra, (3) pleuritis mediastinalis posterior.

3. This distinction is justified, not merely from an anatomic point of view, but because it corresponds closely to clinical facts. Pleuritis mediastinalis anterior sinistra resembles very much exudative pericarditis. The most striking symptom of a pleuritis mediastinalis anterior dextra is a very deep cyanosis of head, neck, thorax and upper extremities. A posterior mediastinal pleurisy will, provided the exudate is deeply situated and is sufficiently large, cause inspiratory stridor and sometimes a deviation of the trachea by pressure on the trachea, dysphagia by pressure on the esophagus, engorgement of the intercostal veins by pressure on the azygos veins, and paroxysmal cough by pressure on the pneumograstic nerve.

1311 La Salle Avenue.

ABSTRACT OF DISCUSSION

Dr. DeLancey Rochester, Buffalo, N. Y.: Although I have nothing to offer in the way of cases to report in support of Dr. Frick's position, I do not believe that such additions to the literature should go without some discussion. We owe him a great deal for his careful analysis of his cases and for the careful examination and the knowledge displayed in making the diagnosis and his confirmation of it by exploration and, whenever possible, by autopsy. The literature on this subject will be greatly added to; we shall all be required to look more carefully into these cases hereafter. When there is cyanosis and difficult breathing, cases that have heretofore been looked on as cardiac, can now be proved to be mediastinal pleurisy, a condition which can be relieved by operative procedures.

Dr. Frank Smithies, Ann Arbor, Mich.: Were any photographic findings registered in these cases?

Dr. Anders Frick, Chicago: No photographs were taken of the anterior mediastinal pleurisies. In a few cases of left posterior mediastinal pleurisy, however, skiagraphs were taken and they indicated a shadow or dark zone to the left of the posterior mediastinum. In these cases, also, there was dulness between the spine and the left scapula.

TRAUMATIC RUPTURE OF THE FIXED PORTION OF THE MALE URETHRA *

OTTO C. GAUB, M.D.
Surgeon, Allegheny General Hospital, St. Joseph's Hospital and Dispensary
PITTSBURG

Traumatic rupture of the fixed portion of the male urethra is a most serious injury, both in its immediate aspect and remote consequences: immediately serious, because of leakage of urine following the several classical paths of extravasation, with subsequent decomposition, or on account of complicating lesions of osseous or soft tissues; remotely so, owing to formation of traumatic stricture, with its attendant urinary stagnation and infection of the entire urinary tract.

The force causing a rupture of the urethra acts in one of two ways—in a direct manner, the patient falling astride an object, or indirectly, the pelvic bones being crushed together, the force usually acting in the coronal plane of the body.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-First Annual Session, at St. Louis, June, 1910.

Produced in a direct manner, the urethral tear may be in a part anterior, within, or posterior to the layers of the triangular ligament, usually without complicating factors. Indirectly produced by crushing force, the tear in the urethra is often associated with an injury to the pelvic bones or soft tissues; these latter may be so disjointed or broken, the pelvic fascia so lacerated and torn from its attachments as to allow the bladder and prostate gland to hang loosely in the pelvis. The tear of the puboprostatic ligaments opens a communication between the space of Retzius and the perineum.

A tear of the membranous urethra, accompanied by laceration of one or both layers of the triangular fascial septum, or a transverse rupture of the urethra at the apex of the prostate gland, are the types of injury found as a result of force acting in an indirect manner.

The signs of a ruptured urethra are patent in the great majority of cases. With a history of an injury as described, coupled with a varying amount of free blood issuing from the urethra, inability to pass urine (when the urethra is completely torn) or difficulty experienced in voiding a small quantity of urine, always preceded by pure blood from the canal (when the tear in the urethra is partial) are extremely suggestive. Attempts made to pass a catheter are futile and usually serve to increase the bleeding.

Depending on the part of the fixed urethra injured, local inspection reveals a fulness and perhaps discoloration of the upper part of the perineum, noticeable at the perineoscrotal junction when the bulbous part of the tube is injured; or the swelling may be confined to the middle of the perineum or about the anal region when the tear is located between the layers of the triangular ligament or posterior to them. The tumefaction is caused by an effusion of blood perhaps mixed with urine. If, for any reason, the lesion is not immediately repaired, infection occurs extending along paths previously mentioned—underneath Colles' fascia through the abdominoscrotal passageway to the anterior and lateral abdominal walls following injury to the bulbous urethra; confined, at first, between the layers of the triangular ligament, subsequently ulcerating either through the anterior leaflet, gaining access to the space bounded by Colles' fascia, or through the posterior leaflet, invading the cellular tissue about the rectum.

The lesion is an anatomic one and requires an anatomic operation for its repair. It is a self-evident proposition that a procedure which restores the parts as nearly as possible to normal, brought about with a minimum of injury to surrounding structures, carrying with it a minimum mortality and shorter period of disability, both immediate and remote, is the procedure of choice. These factors are conserved by performing a circular urethrorrhaphy through a perineal opening, which incision gives access to all parts of the fixed portion of the male urethra.

The operation is greatly facilitated by placing the patient in the exaggerated dorsal position. For this purpose, the old Clover's crutch is used, supplemented by a sand-bag placed under the sacrum, which flexes the pelvis on the vertebral column so as to bring the perineum in the horizontal plane. This position renders the structures taut and makes possible an anatomic dissection. The object of this dissection resolves itself into an effort to find the proximal end of the torn urethra, the distal end being readily located by means of a sound introduced through the external meatus.

When the tear is situated anterior to the superficial triangular ligament, the proximal end of the urethra may be found through the original tear in the accelerator urinæ muscle; or this structure may be split along its median raphe, affording further working room and the end readily found.

When the tear is located at the apex of the prostate gland, the incision through the skin of the perineum may at once open an area filled with clotted blood, or it may be necessary to cut the central tendon of the perineum to reach the site of injury.

It is in those patients suffering from a rupture at the bulbomembranous juncture or situated in the membranous urethra, between the layers of the triangular ligament, that the procedure of retrograde urethral catheterization becomes necessary, rather than a suprapubic cystotomy as an aid in finding the proximal end of the torn urethra. The anatomic landmark sought is the apex of the prostate gland. The technic is similar to that carried out by Young in the performance of perineal prostatectomy, but without a guide. This step is not difficult of accomplishment, by reason of the excellent position of the patient. The urethra, immediately in front of the apex of the prostate, is opened by a linear incision, through which a small sound or guide is introduced from behind forward, facilitating the discovery of the proximal torn end of the urethra.

With both the distal and proximal ends of the ruptured urethra secured, the exaggerated dorsal position of the patient is modified, relaxing the perineal structures, thus aiding the suturing of the anterior wall of the torn canal; then the introduction of a rubber catheter from the external meatus to the bladder, completion of the circular urethrorrhaphy and closing the linear incision in the urethra at the apex of the prostate.

If the general condition of the patient does not warrant the completion of the technic of suturing the ends of the torn canal the catheter will act as a splint favoring the reparative process.

It is observed that following a rupture of any part of the fixed urethra, complicated or not by injury to surrounding structures, a catheter introduced into the bladder through the proximal torn end will evacuate a large quantity of clear urine. This retention is probably due to interference with the nerve-supply of the internal vesical sphincter, increasing its tonicity, a fact of importance, in that primary shock may be combated without the fear of continuous leakage of urine demanding immediate drainage of the bladder.

Perhaps the vulnerating force may be of sufficient degree so to distort and dislocate the perineal structures as to make it impossible to discover the proximal end of the torn urethra. In this case the only resource is to open the bladder suprapubically and carry out a retrograde catheterization. The condition of the patient may contraindicate a complete operation as a primary procedure. This matter of time, type and choice must be determined by the individual operator.

The force necessary to produce an injury of so grave a nature as rupture of the urethra undoubtedly devitalizes tissues, predisposing to infection. This imminent danger may be anticipated by appropriate drainage. If the character of the injury is such as will lead to infection underneath Colles' fascia, a rubber tissue drain of this space emerging through the perineal incision is indicated, or a through-and-through perforated tubular drain from the perineal incision, following the abdominoscrotal passageway on one or both sides, making its exit at the pubes, may prevent a serious and annoying infection.

The wound in the perineum associated with an uncomplicated rupture of the urethra at the apex of the prostate will be cared for with a rubber tissue drain from the site of the rupture to the perineal surface.

When the ligamentous attachments of the prostate are torn, affording a communication between the prevesical space and the perineum, a perforated rubber tube, introduced through a small incision in the median line immediately above the symphysis pubis, passing to one or the other side of the prostate and emerging from the perineal incision, will prove a wise precaution.

REPORT OF CASES

The following cases typify the subject-matter:

CASE 1.—*Patient.*—(Admission 40,078).—J. L. M., electrician, aged 30, was admitted to the Allegheny General Hospital, Aug. 2, 1909. The patient was on a ladder removing electric lamps, when it slipped and he fell astride an iron pipe.

Examination.—This showed on the inner aspect of right thigh a bruise, and also a slight bruise on right side of scrotum. In the median line of the perineum a small tumefaction was observed. The patient suffered very little pain. Blood escaped from the external meatus. Attempts at urination were unsuccessful, producing great distress and increasing, apparently, the swelling in the perineum and area about the anal region. The bladder on palpation was found moderately distended. Attempts at catheterization were unsuccessful.

Operation.—The patient was placed in the exaggerated dorsal position, a sound was introduced and felt at a point posterior to the base of the triangular ligament, a median incision was made from the perineoscrotal junction to within half an inch of the anal fold, the area was opened containing clotted blood, mixed with urine. The entire prostate gland presenting a minute portion of urethra at its apex, was found hanging loosely in the injured area. The structures about the gland were torn and lacerated, allowing the examining finger to be readily inserted into the space of Retzius and palpated through the anterior abdominal wall, immediately above the symphysis pubis. Suture of the anterior wall of the urethra with interrupted catgut sutures, the introduction of a catheter into the bladder and also through the anterior portion of the urethra, evacuation of clear urine, completion of circular urethrorrhaphy, the introduction of a perforated rubber drainage tube through a small median incision immediately above pubes and brought out through the perineal wound, along left side of gland, with closure of skin wound completed the operation.

Convalescence was uninterrupted and the patient was discharged Aug. 21, 1909, nineteen days after the operation. Occasionally there was a slight discharge of urine through the perineal opening which ceased entirely within the next ten days.

CASE 2.—*Patient.*—(Admission 41,820).—C. B., laborer, aged 30, was admitted to the Allegheny General Hospital Jan. 1, 1910. The patient was walking in the street when he stepped on the edge of the cover of a man hole, which turned on end, the patient falling astride it. He was helped home, suffering severe pain in the perineal region and bleeding from the meatus. He went to bed, but was unable to sleep. Next morning he had several chills and suffered severe pain in lower abdomen. A physician was sent for who found the bladder distended to within one inch of the umbilicus. An attempt to catheterize the patient was unsuccessful and bleeding from the canal commenced. The patient was sent to the hospital.

Examination.—Distended bladder was present on inspection and palpation, the area over the bulbous urethra was swollen and discolored; there was bleeding from the external meatus. Temperature was 100.4, pulse 118.

Operation.—The patient was placed in the exaggerated dorsal position and a median incision over the bulbous urethra made. Clotted blood was found underneath Colles' fascia. There was laceration of the fibers of the accelerator urinæ muscle. A sound introduced through the external meatus demonstrated the distal torn end of the urethral canal, but was unable to find the proximal end of the torn tube. The incision was carried back to within one-half inch of anal folds. Blunt dissection was made of the area on either side of the central tendon of the perineum, which structure was cut. Further dissection disclosed the apex of the prostate gland. The urethral canal was opened at the apex of the gland, being careful to grasp the mucous membrane on either side of incision. The introduction of a small sound made it possible to find the proximal torn end of the urethra, which had been severed at the bulbomembranous junction. Introduction of the catheter into the bladder evacuated a large quantity of clear urine. Suture of the anterior wall of the urethral canal, the introduction of a catheter from the external meatus to the bladder, completion of circular urethrorrhaphy, closing of the linear urethrotomy wound, the insertion of a rubber tissue drain from site of tear to perineal surface and closure of the skin incision were the further steps in the operation.

Subsequently it was necessary to pass a drainage tube through the abdominoscrotal passageway on both sides, owing to infection. On this account convalescence was protracted. The catheter was removed on the fifth day. Leakage of urine through perineal wound persisted for four weeks. The patient was discharged from the hospital March 12, 1910. Examination was made June 4, 1910, with the introduction of a 27 French sound without difficulty, revealing a slight roughening at site of tear. The urine was negative.

CASE 3.—*Patient.*—(Admission 41,992).—T. S. S., bridge inspector, aged 53, was admitted to the hospital Jan. 14, 1910. The patient was at work on a bridge when he fell astride a log. He rested about one-half hour, then he resumed work, continuing until time to quit about an hour later. He paid no attention to his hurt. While on the train bearing him to his home he coughed several times and felt as if something gave way at the site of injury. After a short time he noticed that his clothing was blood-stained and on examination found that he had bled freely from the external meatus. On his arrival home Dr. Ray (Glenshaw) who was called to see him, attempted to pass a catheter but did not succeed, after which the patient was sent to the hospital.

Examination.—Patient walked into the hospital about nine hours after the injury. The bladder was found distended, and the external meatus closed by clotted blood, the perineum, scrotum, penis, pubic area and flanks were greatly discolored, almost black, and much swollen. The patient's general condition was good.

Operation.—Patient was placed in the exaggerated dorsal position, a sound introduced into the urethra stopped in the bulbous portion. Median incision over the bulbous urethra revealed a laceration of the accelerator urinæ muscle on left side. The distal end of the torn urethra was readily found but it was impossible to find the proximal torn end. The incision was enlarged and a technic similar to that in Case 2 carried out, the tear was found at bulbomembranous junction. Rubber tissue drain from site of rupture to perineal surface was introduced, also from prostatic area.

The catheter was removed on the sixth day. Convalescence was uninterrupted. Patient was discharged Feb. 5, 1910, twenty-two days after operation. There was a slight leakage of urine at the time of discharge. This ceased within a week, the wound remained closed for ten days and then opened again for a few days, since which time there has been no leakage. On examination June 4, 1910, a 27 French sound was readily introduced. There was slight roughening at point of tear in urethral canal, urine negative.

CONCLUSIONS

1. Rupture at any point of the fixed portion of the male urethra is an injury of grave import.

2. The condition of the patient permitting, immediate operation to restore the integrity of the urethral canal is imperative.

3. Repair of the torn urethra at any point may be done through a median perineal incision.

4. Shock is to be overcome as a primary measure; leakage of urine in the early hours following traumatism is not to be feared.

5. Appropriate drainage is to be instituted as a prophylactic measure against infection.

6. Of great importance in the technic is the proper position of the patient.

924 Westinghouse Building.

ABSTRACT OF DISCUSSION

Dr. Harry M. Sherman, San Francisco: The mechanism by which the urethra may be wounded through a pelvic wound might be explained a little more explicitly. The two ossa innominata may be pressed together, as when force is applied on either side of the body, or they may be forced apart, as when the force is applied antero-posteriorly. If a force presses the two bones together, the urethra may be pinched off between the two descending rami of the pubic bone, or one bone may slide past the other, like the blades of a pair of scissors, thus cutting off the urethra. When this occurs, the urethral injury outranks the injury to the skeleton, and the possible extravasation of urine outranks the injury to the urethra. That is, when this accident occurs the extravasation of urine is the matter of major moment, and the one which requires most attention. The plans which have been detailed for the drainage of the different layers of areolar tissue are ample. Especially would I emphasize that which drains from the space of Retzius down behind the pubic bone, and so out through the perineum. Drainage is the keynote to the situation, so far as my experience goes with these cases.

Dr. George F. Corrigan, Newark, N. J.: Three or four months ago I had a case similar to the one described by Dr. Gaub. This man was going down in an elevator when the car slipped and he fell on a wheelbarrow, rupturing the perineum. He was brought to the hospital and several attempts were made to repair the damaged urethra. The openings in the urethra and neck of the bladder were closed; both operations failed, however. I propose in the next few weeks to operate on this man, and I am glad to have heard this paper. I fear that in doing an operation of this kind we must divert the urinary flow, in order to be successful. After the necessary preparation I will make an inverted Y-incision in the perineum, and dissect the rectum freely from the surrounding structures as well as the urethra, and endeavor to find the opening. I will pass a catheter or grooved staff after denuding the cicatricial tissue around the opening in the urethra, and then attempt to close the latter with chromicized catgut. If I do not go further, the operation will not be a success. I think that the proper procedure is to drain the bladder from above.

Dr. Parker Syms, New York City: Immediate drainage in these cases is the important factor in saving life. Immediate repair of the injury to the urethra is most important, when it can be done with safety. I desire to report what I consider to have been a surgical curiosity—an instance of this kind which came under my observation several years ago. A mining engineer fell astride a rock and sustained rupture of the urethra, with complete retention of urine. He had to travel nine days on mule-back before he could get any surgical aid. In the meantime, he had to rely on his own ingenuity. He constructed a catheter by putting a quill on the end of a reed and after much trouble and pain, he succeeded in relieving himself. The extreme lithotomy position is a great aid in exposing the deep portions of the perineum.

Dr. J. Hartley Anderson, Pittsburg: Rupture of the urethra back of the triangular ligament is one degree of a rupture which we see in fracture of the pelvis in which the prostate is also injured, and in which there is also an extraperitoneal rupture of the bladder. The operation which Dr. Gaub performed with considerable success is probably the most convenient for the lower part of the bladder, the prostate and the prostatic urethra. When there is a rupture of the bladder involving the anterior surface, the result of crushing force, it is necessary to make a suprapubic incision, and any attempt to suture the bladder in any other way will be found to be a difficult procedure. At the same time the suprapubic opening gives us the advantage of draining the prevesical space, and combined with the Proust incision drainage of the deep perineum.

The one thing that we find in these cases of ruptured urethra is the enormous displacement of the bladder where the true ligaments of the bladder are ruptured. We may find that the prostate is shoved up two or three inches, and it is almost impossible to reach it, but by making use of Young's retractors we are able to pull the bladder down and suture it into position. Drainage, especially if there has been extravasation of the urine, or an external perineal wound, is very important. The frequency of pelvic cellulitis is great, and if the fractured pubic bones are exposed, pelvic deformity and pyemia are after the results. Stricture and tortuous urethra are nearly always the final results of complete tears of the deep urethra.

Dr. Hugh Cabot, Boston: The care of these patients is twofold: (1) that required immediately after the injury, and (2) that of the stricture which is a necessary consequence. The most important element in the immediate care, is the provision for proper drainage of the bladder. The most difficult cases are those due to fracture of the pelvis which are not infrequently complicated by rupture of the bladder. Satisfactory drainage may be obtained either by combined suprapubic and perineal operation, or, in the less serious cases by simple perineal section. It has not seemed to me wise to attempt primary suture of the urethra, because of the unfavorable condition of the tissues. If the sutures are placed in the bruised tissue they will not hold and infiltration occurs and the patient is worse off than if a simple perineal section had been done and the stricture dealt with later, if necessary. It is, however, important at the time of the primary operation to restore the continuity of the roof of the canal, if this has been torn across. Unless this is attended to retraction of the cut ends will result in excessive scar and a stricture difficult to deal with. The restoration of the floor should be left to a subsequent time. The essential part of this stage in the operation is the free mobilization of the anterior urethra. The extent to which the urethra can be mobilized without damage to the circulation is surprising. In one case a gap of one and a half inches was closed by mobilizing the anterior urethra up to and somewhat forward of the peno-scrotal angle, the anterior segment being then sutured to the apex of the prostate. A perineal incision in the form of an inverted V gives good access to the prostate and membranous urethra and if the anterior portion of the urethra has been thoroughly mobilized the ends can be brought together without tension. The failures that I have seen after these operations have been due to fear of sufficiently mobilizing the anterior segment; it being believed that the blood supply which comes through the triangular ligament would be interfered with. This does not seem to me to be serious. The placing of an inlying catheter at the time of operation seems to me objectionable on account of the urethritis which it produces, with resulting infiltration, scar tissue formation and increase of stricture. Drainage by a perineal tube is, I think, to be preferred.

Dr. Hugh H. Young, Baltimore: I have had two somewhat similar cases. One was that of a fresh rupture of the urethra which occurred in a young man who was caught between two freight cars and sustained a fracture of the pelvis, and was unable to void urine. I found that there was complete rupture of the urethra just behind the triangular ligament. The space had filled up with blood clots; the bladder and prostate were pushed upward and an immense blood clot lay between them and the triangular ligament. The interesting thing in that case was the fact that the prostate was cut off from the external sphincter, but the bladder still retained a quart of fluid. The prostatic sphincter was sufficient to prevent the escape of urine from the bladder. I brought down the prostate and made an end-to-end anastomosis with the membranous urethra.

In order to avoid urethritis I brought the catheter out through a hole in the perineum, which gave excellent drainage. The catheter was left *in situ* for a week, and primary union was obtained. No sounds were passed. The man came back to me a year later; a sound passed easily showing the absence of stricture. He was in good condition, except that he had lost erectile powers. It is interesting to note that although no sounds were passed in this case a stricture did not form, probably because the suturing was done in the membranous urethra, where there is no surrounding cavernous tissue.

In cases of carcinoma of the prostate in which I have performed an anastomosis of the bladder with the membranous urethra, no stricture has resulted. Recently I saw a young man with a similar injury, who had been treated simply by suprapubic drainage. I found a mass of scar tissue and had to dissect it out before it was possible to make an anastomosis between the prostate and membranous urethra. The operation was much more difficult than in fresh cases, and I cannot recommend too highly immediate operation and suture of the divided urethra in all these cases of complete or almost complete rupture of the urethra.

Dr. Otto C. Gaub, Pittsburg: I searched for a new type of operation, as it had been the custom in Pittsburg to open bladders suprapubically and drain perineally—a retrograde catheterization. These patients remained in the hospital for a long while. There was infection of the cellular tissue in the space of Retzius, and the patients were incapacitated for months. Stricture followed, so that the idea of treating the ruptured urethra in the manner described occurred to me after having gone over the work done by Dr. Young. I followed the description of the operation which he performed for stricture of the urethra, in which he was obliged to do a retrograde urethral catheterization.

The point is well taken, that it may not be desirable to attempt complete suture of the urethra at the primary operation, but I would go so far as to say that we should restore the anterior wall of the canal. The advantage of the operation through the perineum is that we may stop at almost any stage. If the anterior wall of the urethra is reconstructed, the catheter acts as a splint, allowing the reparative processes to go on with very little scar formation.

Another point made by Dr. Young and emphasized in the paper, is the question of retention of urine. It is curious how these bladders will fill up and no leakage occur. In the third case reported in which the bladder was distended as high up as the umbilicus, at the time of operation, nine hours after injury, by putting a catheter into the bladder clear urine was found, showing that in cases of injury accompanied by severe shock, we need pay no attention to the bladder during the first two hours. The patient can be put into better shape and the severe urethral injury then attended to, restoring the canal entirely or in part, as may be indicated.

THE NEW TREATMENT OF SYPHILIS (EHRLICH-HATA)

OBSERVATIONS AND RESULTS

HENRY L. ELSNER, M.D.
Professor of Medicine, Syracuse University
SYRACUSE, N. Y.

If Ehrlich had ceased his labors after giving to the profession his original work on blood, which was an enormous factor in giving stability to the new-born art of hematology, and his studies on immunity, he would have continued to live as one of the masters of medicine. To-day Paul Ehrlich stands before the profession as the greatest living exponent of chemotherapy. His ceaseless labors have been rewarded by the discovery of a remedy, a chemical compound more specific in its effect against syphilis than any other yet introduced.

I am privileged to be able to preface what I have to offer with the positive statement that the bioxidiamidoarsenobenzoldichlorid, or the remedy labeled "606" (being the laboratory brand), is destructive to the *Treponema pallidum* (erroneously named *Spirochæta pallida,* which latter term, because of usage, I shall retain in this paper) and has a prompt and specific effect on syphilitic tissue.

Prompted by the favorable reports which during July and August of 1910 accumulated in the German medical press, I visited Ehrlich at his laboratory in Frankfurt July 12. My visit was most satisfactory. One is deeply impressed by the sincerity and scientific spirit of this man and his uniform courtesy. He is of a decidedly nervous temperament, systematic, continually on the *qui vive.* While engaged in conversation he becomes fascinating. His earnestness is striking at once. The subject which he is investigating has taken full possession of him. The conversation which I had with him led me to the conclusion that he had unbounded faith in the new remedy, but that he recognized the fact that before we are justified in reaching the conclusion that the late effects of syphilis would be entirely prevented by the remedy, we must pass through a long period of probation. As he expressed it "Es muss erst grundlich ausprobirt werden."

Ehrlich understands fully the object of *chemotherapy* —i. e., the production of such remedies as by powerfully affecting parasitic life cause a minimum of danger to the body which harbors them. To this splendid work he is devoting his life.

There are those who contend that Ehrlich's experiments are made only on mice and rats; but he has made clear that in order to reach safe conclusions all of these chemical products must first be tried on a variety of animals and that the remedy which after animal experimentation produces the most telling results is in all likelihood, after cautious dosage and thorough observation, the remedy which when given to man for therapeutic purposes will be likely to produce similar results. This conclusion was fully justified after animal experimentation at the Ehrlich laboratory with the various arsenic preparations, more particularly the arsenophenylglycin against trypanosomiasis, and the arsenobenzol against spirillum disease. The latter is the "606" of to-day, originally elaborated by Bertheim and used to destroy the spirillum of recurring fever by Hata and finally introduced by Ehrlich, Hata and Bertheim against the *Spirochæta pallida.*

Ehrlich has further convinced the profession that it is not possible in man to begin the use of poisons in the largest corresponding dose which is well tolerated in the animal *(dosis maxima bene tolerata).* In man we have idiosyncrasies to consider. The primary susceptibility and the acquired susceptibility offer the greatest obstruction to the use of poisonous drugs, and it is an uncontrovertible fact that all remedies which destroy living organisms in the blood or in the tissues of the body are poisonous. It has long been known that there are a number of poisons which nullify or completely destroy specific germs but the dose required, it has been found, is so large as to make it destructive to the host or to the individual organs; hence it is useless. It has been pointed out that poisons, to be of use in the economy against parasitic life, whether vegetable or animal, must leave vital organs undamaged just as do the antibodies. The further fact has become clear that remedies which destroy the living parasite must attract these offenders, "anchor" them; in other words, they must be parasitotropic. These same remedies are also organotropic; they are destructive to organic tissue; hence poisons to be of value chemotherapeutically must of necessity continue parasitotropic while the organotropic action must remain negative. The opinion is erroneously held by many that the spirochete is a blood-parasite. Leading syphilographers now hold that there is in all probability but one grand procession of the invading army of spirochetes through the blood-stream. Recent repeated examinations of the blood by Wechselmann, Loewenthal and Canon, seem to corroborate this conclusion. There are but few authoritative reports in medical literature which prove the continuous presence of the spirochetes in the blood. These parasites settle in the tissues of the body, causing in some cases and at some time, as a rule, a local reaction; in other cases no reaction follows, hence no late lesions.

Experience shows that the spirochete, or possibly its product, often resists specific treatment and this is unquestionably the case of tertiary lesions.

THE EHRLICH-HATA REMEDY—DOSE—PREPARATION FOR INJECTION

The drug "606" is a yellow, sulphur-colored powder. Its chemical formula is $C_{12}H_{12}O_2N_2As_2$. Bertheim elaborated the remedy. The average dose for men is 0.5 gm.; for women 0.45 gm. There is a tendency to increase this dose to 0.6 gm. in women and 0.8 in men. In all probability it will be found that the larger dose will be well borne and relapses will be reduced to a minimum. The dose for children ought not to be higher than 0.02. Wechselmann injects nursing babies with doses varying from 0.01 to 0.015 and even higher, and says that he has had no bad results. Certainly the clinical material which he presented abundantly proved the truth of his statement.

One would naturally suppose that it is easy to prepare the remedy for either intramuscular or intravenous injection. I myself shared this opinion with others who had never seen it used. Before Ehrlich sent me the remedy, after I wrote him that I was soon to leave Germany, he wisely suggested that because of the great difficulties of preparation those who were to use it might with profit visit some one of the leading centers of Germany where there was a large clinical material for the purpose of learning the method of its mixture, and the injection technic. In a letter received on August 10, Ehrlich suggested either Vienna, Berlin, Breslau or Magdeburg. I selected Berlin, where I visited at the Rudolph Virchow Spital, the clinic of Wechselmann, who has unquestionably had more experience with the use of "606" than any other man in Germany, and the Kraus clinic at the Charité, in which Citron had full charge of the material. The name of Citron is familiar to Americans who have visited medical Berlin. He is a genial, earnest worker and a delightful gentleman, thoroughly interested in his work, an excellent teacher and in all probability one of the best laboratory men on the Continent.

Wechselmann had injected over 600 patients before I left Berlin. The material at the Charité was not so large as that at the Rudolph Virchow Spital. Intravenous injection was not the favorite method of introducing the remedy in Berlin. At the Wechselmann and Kraus-Citron clinics the intramuscular method as originally recommended by Ehrlich was used. Ehrlich has recently reversed the first directions given and now recommends the intravenous method as more likely to prevent relapses and the late manifestations of syphilis, and agrees with those who claim prompter results than follows the intramuscular treatment.

METHOD OF PREPARING "606" FOR INTRA-MUSCULAR INJECTION

The entire method must include strictest asepsis; all glassware, everything used, must be thoroughly sterilized. The powder is emptied into an agate mortar, about 2 c.c. of a normal solution of sodium hydroxid is added and thoroughly mixed with the powder; a yellow thick alkaline fluid results. The alkalinity must be overcome by acetic acid. I have found it best to use the 1 per cent. solution of acetic acid instead of the glacial acid, using a little less than 0.5 c.c. of the former. If too much acetic acid is added it is necessary to overcome the acidity by a further addition of the sodium hydrate solution. In Berlin glacial acetic acid is used. If too much alkali is added to overcome the acidity after the addition of the acetic acid, then the 1 per cent. solution of acetic acid is again slowly added. The object, to reach a point at which the reaction will be absolutely neutral, must be kept constantly in mind. Litmus paper is used to test the reaction. It is wise, when it is neutral, to empty the preparation into centrifuge tubes. In preparing the remedy for injection, in order to save loss I have found it convenient to use the normal salt solution for holding in suspension the remnant left in the mortar and on the pestle. All of this is thoroughly centrifugalized. A light yellow colored powder is precipitated, after thorough sedimentation the supernatant fluid is removed by means of a pipette, and normal saline solution is added to hold the "606," which is withdrawn into a Record syringe. It is wise to suspend the remedy in at least 10 c.c. of saline fluid. The use of the normal saline for cleansing the mortar, spatula and pestle to prevent the loss of "606" which would otherwise remain and thus reduce the dose needed, has not been mentioned by others. I am thoroughly satisfied with this method of preparation because by its use I find less pain and less local irritation than I saw in Berlin.

THE PREPARATION FOR INTRAVENOUS INJECTION

Ehrlich has recently sent a circular letter to those to whom he has given "606," recommending the intravenous injection after the method fully described by Schreiber.[1] The method is as follows:

> Into a graduate holding 250 c.c. drop 10-20 c.c. of sterilized water. Add the required dose of "606" and mix thoroughly until there is a clear solution; add sterile water, or better, normal salt solution to the 100 c.c. mark; then add *pro* 0.1 of "606," 0.7 of normal sodium hydroxid solution and mix thoroughly until the precipitate is thoroughly redissolved. If after thorough mixture the solution is not clear add a few drops of the sodium hydroxid solution to produce this and then add sufficient normal salt solution to make 200-250 c.c. The fluids used are all to be warm. The alkaline mixture is then ready for injection. The Cassell syringe and apparatus (or the Weintraub) supplied for this purpose are preferable, for by their use the dangers of introducing air are reduced, if the operator continues cautious and follows the directions given in the original paper of Schreiber.
>
> It must be understood that all of the chemicals used in the preparation of the injection are to be kept thoroughly sterile.

I must repeat the warning of Ehrlich; unless the method of preparation of the remedy is to be materially simplified in the future no one should undertake its introduction into the body without first seeing the experienced mix and use it. I have seen Wechselmann's assistant work almost an hour before his mixture was neutral: Citron averaged between fifteen and twenty minutes in reaching that point. We succeeded in neutralizing the mixture in twenty minutes at our clinic when using the glacial acetic acid; with the 1 per cent. solution originally used by me we have prepared the mixture for the centrifuge in four minutes. It is as easy to prepare the mixture for a number of injections as it is for one.

---

[1] München. med. Wchnschr., 1910, No. 39

I consider the use of the centrifuge in connection with the preparation of the remedy for intramuscular injection of great importance. This, I believe, was first suggested by Wechselmann.

I found that the patients in Berlin were given their choice of the seat of injection, choosing between the inframammary, the interscapular and the gluteal regions.

The patient's skin is to be as aseptic as if he were to undergo an operation. We have insisted on hospital care of all patients injected because of our limited experience with the remedy, and because Ehrlich in his final instructions insisted that we do not use the remedy on ambulatory material. This precaution I believe wise and necessary as my experience grows. The surface, after having been treated in the usual way, is painted with tincture of iodin. We have used no local anesthesia, but use a well-made and sharp needle of large caliber.

I saw several hundred of these patients while in Berlin; some had been injected, some were injected in my presence, and the best place for injection seems to be in the interscapular region. Immediately following the injection there is likely to be some pain. As the method of preparation is improved, the liquid made neutral and the remedy sufficiently diluted, we find pain reduced to a minimum. In the patients whom we have injected we have had no marked local reaction; there has been no redness, but little swelling, and only two patients required a small dose of morphin hypodermatically for the relief of the pain. These patients were hyperesthetic.

At the Wechselmann clinic were found a number of local reactions in which the skin was red—had an erysipelatous hue. From seven to fourteen, sometimes twenty-one, days after injection there was a distinct tender, fluctuating tumor, which might easily be mistaken for an abscess. It has been found, however, that no pus is present in these cases; that the injection does not lead to suppuration. In the patients thus far treated in Syracuse we have not found these persistent swellings; neither has the slight thickening which continues for several weeks proved annoying.

It is hardly necessary to repeat the histories of the patients injected at our clinic and in private practice. The improvement in all of those in which there were evident and palpable lesions has been surprisingly rapid. There are a few points of interest, however, in connection with some of these cases which I should like to mention.

In one of our patients on the eighth day after injection, without previous temperature above 100.2 F., and this only on the second day after injection, there was presented a temperature of 102 F., pulse 110, without return of syphilitic lesions. All specific lesions had disappeared. For three days he vomited at short intervals. There was no abdominal pain; no diarrhea; there were no physical signs. On the fourth day of these symptoms his temperature was 102 F., pulse 80, respirations 20. At 10 a. m. on the fifth day his temperature was 104 F., pulse 110, respirations 21. He had no diarrhea. His bowels were thoroughly emptied by a saline injection. At 1 p. m. his temperature was 102 F., pulse 82, respirations 20. On the sixth day his temperature was 101 F., pulse 80 and respirations 20 at 10 a. m. At 1:15 p. m. the temperature was 99 F., pulse 78, respirations 20; no recurrence of specific lesions. The highest temperature on the seventh day was 100 F.; on the eighth his entire body was covered with a rash which resembled the eruption of measles. There were no catarrhal symptoms referable to the bronchial tubes or nasal passages. The rash faded in three days. The patient on the twelfth day seemed perfectly well and was hungry. There were no evidences in the mouth, glands or on the skin of syphilitic lesions. The urine during this entire period was normal.

The symptoms might easily be explained on the theory that the death of the spirochetes produced endotoxins sufficient to poison the patient. The condition was not alarming at any time but gave us cause for reflection.

This experience has not been paralleled in my practice. In looking over the literature of the subject, however, I find that a number of injected patients have passed through afebrile periods which have been followed by a train of symptoms similar to those in the case reported.

It is surprising to note how promptly the enlarged glands in all recently infected patients disappear after the injection of the remedy and how deep and painful cracks are healed, promptly becoming painless.

In another case of tabes with continuous crises which we were prevailed on to inject we found before injection a negative Wassermann reaction which became positive within three days after the treatment. Similar experiences have been noted by others.

It is surprising to note how promptly the lesions of malignant congenital syphilis yield to the remedy. We found a boy aged 14 in our service, who had been thoroughly treated for deep and characteristic ulcers of the posterior pharyngeal wall with the older remedies for months, who yielded to arsenobenzol in less than seven days. The change in the appearance of the ulcers was striking before the end of thirty-six hours.

In a number of puzzling cases, particularly of skin lesions, we have used arsenobenzol for differential diagnosis with telling and satisfactory results. *Lesions which are syphilitic, palpable and visible, yield to the remedy. Lesions which do not so yield are not syphilitic.*

In all cases the general condition of the patients shows marked improvement: all are more buoyant; are taking on flesh, and look with hope to the future.

All of our cases emphasize the truth of Wechselmann's statement that the changes are so prompt that the lesions twenty-four hours after injection in the majority of cases are no longer satisfactorily demonstrable.

CONTRA-INDICATIONS TO THE USE OF "606"

Personally with my present limited experience I would refuse absolutely to inject any patient outside the walls of a well-appointed hospital, sanitarium or a home where thorough asepsis can be observed.

Sickness of any kind, particularly acute infections, however slight, including ordinary colds, bronchial disturbances and acute indigestions positively contra-indicate the use of "606." Ehrlich writes that patients with metasyphilitic diseases at the present time ought not to be injected because of the fact that a large number of these have already been injected and he wishes to gather the reports of the end results of the treatment before recommending the remedy for these conditions.

Degenerative diseases of the nervous system *far advanced* not only contra-indicate the treatment, according to Ehrlich, but offer direct danger. These include cases of paresis and locomotor ataxia, with associated optic neuritis., Under no circumstances are patients to be injected who have optic neuritis or other pathologic changes in the background of the eye. In these cases there is danger of sudden increase of ocular lesions or arsenical blindness. Aged and decrepit patients with advanced organic disease of vital organs, particularly affecting the cardiovascular system, arteriosclerosis, aneurism or cerebral apoplexy should never be injected. All organic diseases of non-syphilitic origin offer contra-indications.

In spite of these contra-indications which have received the sanction of Ehrlich, which in fact are insisted on by him, I saw in Berlin at the Wechselmann clinic one case of locomotor ataxia with optic neuritis in which the eye symptoms were not increased by the injection and in which the patient was thoroughly satisfied with the result. One case of tabes in which I gave an injection without bad results should in all probability be included among those which offer decided contra-indications. I believe that as our experience grows and we find that no direct harm comes to the patient from the injection in cases of incipient degenerative disease with continuous pain, we shall be justified in yielding to the strong temptation of using the remedy.

At no time should we forget that we are dealing with a poison; and I must again insist on emphasizing with all my force the very important fact that no patient is to be injected unless he continues to remain under the observation of the physician at least seven to fourteen days, preferably the latter time, and that no physician has a moral right to use the remedy unless he has acquainted himself thoroughly with the method of its mixture for injection.

THE WASSERMANN REACTION

Alt in his original work with arsenophenylglycin proved that the Wassermann reaction in syphilitics ultimately became negative. Wechselmann, Lange, Iversen and most observers who have used "606" are agreed that all patients with syphilis treated with arsenobenzol who are observed a sufficient time ultimately present a negative reaction. The only exception which was reported by these observers was in a nursing babe injected on March 17 with 0.02 gm. of "606" who died of intercurrent disease on the eleventh of June without change from positive Wassermann. The symptoms were all relieved. The necropsy showed no syphilitic remnant. In children, particularly young children, the negative Wassermann shows itself later than in adults. In a number of cases in adults and children a negative Wassermann has been followed after treatment by a positive reaction. In some this positive phase continues during a number of weeks, finally yields, becomes negative and remains so.

Statistics of collected cases prove that in patients who have been observed fifty days or longer 84.6 per cent. give a continuously negative Wassermann (Schreiber and Hoppe).

Of 268 patients who presented with a positive Wassermann, treated with the Ehrlich-Hata remedy, 153 became negative in from four to five weeks; eighteen cases, including one of malignant syphilis and one of locomotor ataxia, negative at the time of the injection continued so. It must be remembered that the majority of these patients had been treated with mercury or the iodid or by both, hence the negative Wassermann. In a number of cases in which the Wassermann became negative and then became positive, a second injection was followed by a continuous negative phase. As a rule the cases which become positive after the injection, if there are no evidences of active syphilis, finally merge into the negative state.

A positive Wassermann in any case is to be interpreted as evidence of constitutional syphilis, either hereditary or acquired. A negative Wassermann does not exclude the possibility of syphilitic infection.

It is surprising to note how many positive Wassermanns we are unearthing in conditions in which we have never before been able to demonstrate the true pathogenesis, though often strongly suspected. In Germany, particularly in Berlin, Citron and others are finding a surprisingly large number of positive Wassermann reactions in cases of cardiovascular disease. A large proportion of non-inflammatory aortic valvular and degenerative lesions have thus been shown to be due to syphilis.

The Germans have not departed from the original Wassermann technic and Lange makes the positive statement that the principles included have not yet been successfully replaced by other methods and must be rigorously followed.

VARIETIES OF LESIONS

The material which has justified this publication included a large number of malignant cases observed at the hospitals already mentioned which had been rigorously treated during long periods with our usual remedies, and under favorable conditions, without yielding. Among these were found deep-seated ulcers, cracks and thickenings about the genitals, syphilids affecting the scalp, faucial syphilis, syphilitic leukoderma, malignant types of congenital syphilis and serpiginous syphilids. None of these failed to show a favorable response to treatment. Not all of these, however, presented after treatment with entire disappearance of the lesions; occasionally a small nodule or ulcer remained. This was more likely to be true of the cases which were treated during the early days of "606," when smaller doses of the remedy were used than were finally found necessary. Wechselmann believes that in some of these cases in which the full dose was given and in which remnants remained, there is a syphilitic endarteritis which blocks the entrance of the remedy to the diseased area. In a number of these cases he administers the iodids during a limited period, believing that it opens the avenue through which the remedy reaches the distant lesion. I saw a number of these cases in which a second injection was followed by the prompt disappearance of the lesions. In a number of cases treated by Wechselmann there were positive evidences of relapse and a reappearance, more particularly of cutaneous lesions. He believes that this was due to either an insufficient dose or to the malignant nature of the infection, and in these cases he recommends a second injection after a reasonable period of observation, usually from six to eight weeks. Rupia yields to the treatment, as a rule, in from seven to fourteen days. At the Magdeburg clinic syphilitic epilepsy has been favorably influenced.

My observations justify the administration of arsenobenzol for the removal of gummata wherever located. Cases of brain, liver, and cutaneous deposits yield, in fact, melt away, after the injection. For brain gummata, when the diagnosis is made early, the treatment promises the prevention of the ultimate destruction of invaded tissue. Large liver gummata which threatened life have been cured in a few days. Kakeles reports a case in which exploratory operation disclosed the presence of an enormous non-operable mass, which proved to be a gumma of the liver, which was successfully treated with "606." The reporter says, "I have never seen a pathologic mass melt away so rapidly." No visible or palpable syphilitic lesion which I have seen has failed to be promptly influenced by the remedy.

It is safe to inject pregnant women who are syphilitic; the fetus is favorably influenced by the treatment as has been proved by several observers.

HEREDITARY SYPHILIS

Ehrlich reported at a recent meeting of the Aerztlicher Verein in Frankfort that hereditary syphilis can be cured by injecting the mother of the nursling without direct treatment of the babe.

Taege reports brilliant results in a case in which a syphilitic mother aged 19 gave birth to a babe which promptly developed pemphigus syphiliticus, nasal syphilis, paronychia syphilitica and other positive symptoms of syphilis. The mother was injected ten days after confinement and nursed the babe. For two days the symptoms in the babe increased; after five days the history showed that the lesions were all yielding and in fifteen days after the injection of the mother the babe had gained 1,400 gm. and was free of all signs of syphilis. The examination of the mother's milk failed to show the presence of organic arsenic and on the addition of hydrochloric acid and potassium chlorate only a faint trace of inorganic arsenic was discoverable.

Ehrlich believes that the sudden death of the spirochetes releases a large quantity of endotoxins which in turn are responsible for the formation of an antitoxin which is present in the mother's milk. Whether due to arsenic or to the antitoxin finally liberated, the results are positive and surprising.

Ehrlich is less disturbed by the direct effect of the arsenobenzol in the new-born babe than by the poisonous effect of the endotoxins resulting from the death of the millions of spirochetes which flood the body.

The rational treatment of congenital syphilis makes it necessary for the mother to nurse her babe, and that she be injected with "606" without delay. When this is impossible "however paradoxical this may be," Taege says, "the syphilitic nursling must have a syphilitic wet-nurse who has been treated with '606.' "

Meirowsky and Hartmann prompted by Taege's, Duhot's and Ehrlich's observations have used the blood-serum of injected mothers in the treatment of congenital syphilis with decided benefit, and they feel justified in concluding that the results would have been entirely satisfactory if they had had a sufficient supply of the serum. Examination of the serum injected showed traces of arsenic. They believe that the antitoxin in the serum and the small quantity of arsenic are in all likelihood responsible for the results obtained. This opens a new field of study which promises to lead to the early and prompt control of the ravages of congenital syphilis.

THE DESTRUCTION OF THE CONTAGIUM VIVUM

Unquestionably the most important, most far-reaching effect of "606" to mankind is its power of destroying the living contagion or the *Spirochæta pallida*. This at once places syphilis among the diseases which will ultimately be effaced, and that with more ease than any of the other infections. Syphilis becomes a controllable and preventable disease.

The injection of the subject is followed in from seven to ten days by the complete disappearance of the parasite. Süsskind places the time of its death at from six to seven days.

Iversen has experimented with chancre-juice removed by the Bier method to find that without exception the *Spirochætæ pallidæ*, which were originally demonstrated, had disappeared in two or three days after the injection. Better proof of the disappearance of the spirochetes was found by the same observer in his examination of the inguinal glands of ten patients, in all of whom spirochetes were present before the injection of "606." In three to four days after the treatment there were no demonstrable spirochetes in the same glands. Iversen concludes that if after five or six days in injected patients spirochetes are found in the inguinal glands complete sterilization has failed to follow and the patient must be subjected to a second injection.

INTRAMUSCULAR AND INTRAVENOUS METHODS

The relative advantages of the intramuscular and intravenous methods of introducing the Ehrlich-Hata remedy are being considered. As already mentioned, Ehrlich recommended the intramuscular injections until recently, when he became convinced that the intravenous is decidedly better. The experiences of Iversen and others are convincing. It is certain that the intravenous method is followed by the more prompt elimination of the arsenic, requiring four days, while with the intramuscular method this may continue for fourteen days. The pain, which by the newer method of mixture is materially reduced, is hardly to be considered a serious objection to the intramuscular method. The intravenous injection is almost always followed in two to three hours by chills, which continue at least thirty minutes, accompanied by elevation of temperature, aching, malaise, vomiting and diarrhea. Complications are not likely to follow in well-selected cases with either method if the necessary precautions are observed.

In malignant cases it has been suggested that the two methods be used together. It is best to give intravenously the largest possible safe dose in malignant cases at the present time. Unquestionably our methods will be materially simplified in the near future. I have heard of but one death attributable directly to the remedy in all of the thousands injected. It must be remembered, however, that the material has been carefully selected and the remedy has been in the hands of but few, and all under the instruction and guidance of Ehrlich, to whom we are morally responsible for every patient injected.

The reports which are presented may appear to those who have not seen the results of treatment to be unduly rose-colored. It is true that one can scarcely believe his eyes while watching the wonderful change which takes place in these lesions. Iversen of St. Petersburg says that it is naturally difficult to describe the effect of arsenobenzol on the lesions of syphilis. "These," he says, "must be seen and palpated that the result of the treatment may be thoroughly appreciated."

CONCLUSIONS

My experience with the remedy as I saw it used abroad and in my own private and hospital practice justifies the following conclusions:

1. The *treponema*, otherwise known as the *Spirochæta pallida*, is positively destroyed and the living contagion of syphilis is promptly removed by the Ehrlich-Hata remedy.
2. The preparation "606" promptly and favorably affects visible and palpable syphilitic lesions. It also removes deep-seated gummata.

3. The remedy stays the destructive and onward march of syphilitic ulcerations and causes their healing in a surprisingly short time.

4. It is more rapid in its effect on specific disease than any other known remedy.

5. It is likely to prove more valuable than any other remedy in the treatment of the specific diseases of most internal organs.

6. It cannot replace cicatricial tissue, the result of Nature's reparative processes; neither does it affect favorably chronic degenerative diseases of the nervous system, such as paresis, system-diseases of the cord, in which there is a break in the continuity of nerve structure, though in some cases it seems to influence favorably the continuous crises of locomotor ataxia.

7. In all cases it causes a leukocytosis and the formation of antibodies.

8. It materially modifies, and in most cases ultimately negatives, the Wassermann reaction.

9. It unquestionably floods the circulation with endotoxins resulting from the death of millions of spirochetes, and in all probability an antitoxin is developed in the blood-serum. These facts must be thoroughly considered in connection with the treatment.

10. In acute and threatening deposits in vital organs the effect of "606" will often prove life-saving because of its prompt action, and for that reason it is preferable to the iodids or mercury.

11. It ought not to be given to ambulatory patients; neither is it safe in the hands of the careless or those who have not seen it used and learned the difficult method of its preparation for injection.

12. The hospital, where all things required in the preparation of the mixture of "606" can be sterilized, and where the centrifuge can be used, is preferable to any other place for its injection.

13. Patients injected should be kept quiet and in bed during seven days under close observation, and for a longer period if indications demand.

14. Second injections, if indicated, should not be given in less than eight weeks after the first.

15. Contra-indications should be carefully considered before using the remedy. Patients with any other infection than that of syphilis should not be injected, however mild the former may be, until a safe period has lapsed after their recovery; neither should the feeble or old or those with other than syphilitic organic disease be injected.

16. Congenital syphilis demands the treatment, either directly or indirectly, as suggested in the paper.

17. The living contagion is destroyed by "606"; hence its early use can prevent the spread of syphilis. This subject demands the immediate attention of sanitarians and those directly interested in public health.

18. In occasional well-selected cases the use of the iodids after the method of Wechselmann will increase the efficacy of "606" when second injections are necessary. From two to three weeks should lapse after thorough mercurial treatment, when this has been used, before the injection of arsenobenzol.

19. In spite of the fact that nearly all agree that the effect of arsenobenzol is magical, sufficient time has not lapsed to justify the conclusion that a single injection of "606" will prevent what we now recognize as the secondary and tertiary stages of syphilis. Only after long years of careful observation shall we be able to reach a positive conclusion. It will be necessary therefore to keep injected patients under close observation.

406 East Genesee Street.

THE CULTIVATION OF TISSUES OF THE CHICK-EMBRYO OUTSIDE THE BODY *

MONTROSE T. BURROWS, M.D.
NEW HAVEN, CONN.

In 1907 Harrison described briefly before the Society of Experimental Biology and Medicine[1] a method which he had found successful for the growing of certain tissues of the frog embryo outside the body. Essentially the method consisted in dissecting the central nervous system, myotomes and skin of frog embryos free from the surrounding tissues and transplanting them to a drop of lymph taken from the lymph-sac of an adult frog and contained within a hollow slide. The lymph immediately clots about the tissue elements into a loose fibrin network. Harrison watched the growth of the axis-cylinder processes of nerves and the proliferation and wandering of epithelial and connective-tissue cells within this matrix. He further observed striated embryonic muscle cells to become differentiated from the preexisting cells of the myotomes. In other words, he was able to observe a certain amount of differentiation of the tissues over a short period of time.

Other fluids were employed, however, without success, viz., physiologic salt solution, Locke's solution, and gelatin; and the transplantation of the embryonic tissues to the ventricles of the brain of the frog was not followed by proliferation and development. It appears as though the fibrin network was essential in order to afford a supporting framework on which the cells can attach themselves and thus retain their tension. The fluid within the meshes of the network corresponds to the fluid bathing the cells in the living animal and provides the nutriment. The full details of Harrison's work are now in press and will appear in the *Journal of Experimental Zoology,* 1910. In the spring of 1910 Professor Harrison kindly permitted me to spend a few months in his laboratory in order that I might acquire under his own supervision the method of growing tissues outside the body. He had already concluded that lymph was not a wholly satisfactory medium for growth. Some of the reasons were the following: The clots produced from it were neither firm nor uniform. Small quantities of lymph could be obtained from a single animal that sufficed only for one or two preparations. Hence, large series of control preparations could not be secured. It became necessary, therefore, to obtain a more uniform and abundant medium in order that the conditions underlying the growth and differentiation of tissues might be subjected to close analysis. Such an abundant medium of constant composition would, theoretically, be supplied by the blood-plasma provided it could be obtained in suitable condition.

The particular object of my study with Professor Harrison was to adapt, if possible, his method to the investigation of the growth of the tissues of warm-blooded adult animals in order to continue and extend the study of the laws of the healing of wounds and regeneration of nerves, which subjects were at that time being actively studied by Dr. Carrel, with whom I was associated at the Rockefeller Institute.

In repeating the original experiments of Harrison I succeeded in substituting the blood-plasma of the adult frog for the lymph, and thus in overcoming some of the chief drawbacks which Harrison had encountered in his earlier work. The attempt was then made to cultivate tissues of chick embryos. The embryo of the chick offered the especial advantage of being procurable at any time throughout the year, and provided the opportunity for making observations on a warm-blooded species. Moreover, the tissues of the chick embryos are nourished at an early period from an extra-cellular yolk through the means of a well-established vascular system. Hence the removal of pieces of tissue from the embryo interrupts the vascular connections and eliminates all the nutriment derived from the yolk, so that opportunity is afforded not only for the study of growth of tissue, but also of problems of self-nutrition.

TECHNIC

The technic employed consists in placing a carefully isolated fragment of tissue of the chick-embryo in a drop of uncoagulated plasma derived from a chicken on a cover-glass. The cover-glass is inverted and sealed to a hollow slide and the preparation incubated at 39° C. The plasma immediately coagulates about the tissue and holds the fragment firmly fixed in a fibrin network. Preparations made in this way can be readily observed at all time under the microscope.

The success of the method depends on maintaining absolute asepsis and preventing undue chilling of the embryos or the completed specimens either during preparation or the later observation. In excising the fragment of tissue from the embryos they were floated in Ringer's solution and the operation carried out under a binocular microscope covered with an oven heated to 39 C.

The blood for the preparation of the plasma was obtained from young healthy adult chickens under ether anesthesia. The carotid artery is exposed and a cannula previously sterilized in olive-oil is inserted. The blood is collected in sterilized, paraffin-coated tubes which are cooled immediately by being plunged into an ice saltbath. The blood is next centrifugalized by placing the tubes in larger centrifuge tubes which contain a mixture of salt and ice. The supernatant plasma is removed by means of paraffin-coated pipettes and transferred to paraffin-coated receptacles which are kept in a refrigerator until used. The plasma so obtained is highly stabile and can be preserved in a fluid state for many days or even weeks. It should be stated, however, that in making control experiments plasma over four days old should never be used.

RESULTS

The method as described was employed especially during the past summer in the study of the growth of tissues of sixty-hour-old chick embryos. For this purpose isolated neural tubes, heart myotomes, and skin were employed. The results which we obtained can be stated briefly as follows:

The most actively growing elements in the preparations is the interstitial connective-tissue cells. These cells begin to spread into the plasma either as single cells or a layer of cells between the second and twelfth hours of incubation, as a rule, and the growth continues for from six to fourteen days. It often happens that a large part of the drop of fluid is filled with these cells. On being fixed and stained the preparations show mitotic figures to be very common in the proliferating cells. The muscular elements grow much less frequently and cellular outgrowths from them were observed in only about 3 per cent. of the experiments. The outgrowths take place from the myotomes and the heart and appear in the form of short chains of striated cells. The striated cells which are *outgrowths from the heart contract* rhythmically along with the portion of the heart from which they arise. The outgrowth from the nerve cells consists of long axis-cylinder processes which present the same morphologic appearances and react in the same way to specific nerve stains as those of the chick-embryo. The full account of these studies will appear in a forthcoming number of the *Journal of Experimental Zoology.*

The technic as here described for the frog and chick embryos has now been applied by Dr. Carrel and myself to the cultivation of tissues derived from embryonic and adult mammalian species, as has already been described in THE JOURNAL.[2]

I wish to express my great obligation to Professor Harrison, first for extending to me the privileges of his laboratory for the purpose of studying the method which he had developed for growing animal cells outside the body, and next, for the ready personal assistance which he gave me at all times. I wish also to thank Professor Mendel and Professor Rettger for permitting me to use the chemical and bacteriologic apparatus needed for this work.

THE RENAL ACTIVITY IN PREGNANT AND PUERPERAL WOMEN AS REVEALED BY THE PHENOLSULPHONEPHTHALEIN TEST *

F. C. GOLDSBOROUGH, M.D., AND F. C. AINLEY, M.D.
BALTIMORE

Rountree and Geraghty[1] have recently recommended the use of phenolsulphonephthalein as a means of determining the functional activity of the kidneys, and consider it greatly superior to methylene blue, rosanilin, indigocarmin and various other substances which have heretofore been used for that purpose.

The results which they obtained by its means were so satisfactory that we were led to hope that similar determinations might throw further light on the prognosis and treatment of certain cases of toxemia of pregnancy by showing some characteristic change in the functional activity of the kidneys. As it is known that marked alterations in the metabolism normally occur in the maternal organism under the influence of pregnancy and the puerperium, we subjected a number of normal pregnant and puerperal women to the test in order to determine to what extent their kidneys reacted to it, before applying it under diseased conditions. We employed the technic recommended by Rountree and Geraghty, which is as follows:

> Twenty to thirty minutes before administering the test the patient is given 300 or 400 c.c. of water by mouth in order to insure free urinary flow, as otherwise a delay in the appearance of the drug in the urine might be simply due to lack of secretion. The bladder is then completely emptied by means of a catheter introduced under aseptic precautions, and 1 c.c. of a carefully prepared solution containing 6 mg. of phenolsulphonephthalein to the cubic centimeter is administered subcutaneously either in the arm or the buttocks by means of an accurately graduated syringe. The time is

accurately noted, and the urine as it is secreted is allowed to drain through the catheter into a test-tube containing one drop of a 25 per cent. sodium hydroxid solution, and a note made of the time elapsing until the appearance of the first faint pinkish tinge. Each sample of urine is measured and the specific gravity taken. A sufficient quantity of 25 per cent. sodium hydroxid solution is then added to make the urine decidedly alkaline so as to elicit the maximum color, as acid urine only becomes yellowish or orange, which immediately gives place to a brilliant purple red when it becomes alkaline. The sample is now placed in a liter measuring flask, mixed thoroughly with distilled water and accurately filled. A small filtered portion is then taken and compared with the standard used in all these determinations. This consists of 3 mg. of phenolsulphonephthalein diluted up to 1 liter and made alkaline by the addition of 1 or 2 drops of 25 per cent. sodium hydroxid solution, and forms a beautiful purplish red fluid, which retains its intensity of color for an indefinite period, so that a single preparation serves for an immense number of tests. On comparison of the diluted alkaline solution with the standard by means of a Duboscq colorimeter, the percentage of the drug eliminated is readily estimated.

Rountree and Geraghty obtained the following results in normal non-pregnant individuals:

> In normal cases the drug appears in the urine in from five to ten minutes, and 40 to 60 per cent. of the 6 mg. dose (the average being about 50 per cent.) is recovered in the first hour. From 15 to 25 per cent. of the drug administered is recovered in the second hour, making the total recovery for the two hours 61 to 85 per cent. We do not consider the time of the total elimination as of as much value as the amount of elimination for a definite period.

We have applied the test to ten women in the last month of pregnancy and to eleven women in the first two weeks of the puerperium, who were under observation in the obstetrical department of the Johns Hopkins Hospital. As far as could be shown by routine physical examination, urinary analysis and the course of pregnancy and the puerperium, all of them were normal. Twelve observations were made on the ten pregnant women, and one on each of the eleven puerperal patients; while the only variation from the technic of Rountree and Geraghty consisted in making the injections deeply into the muscles of the buttocks instead of into the arm; and we might add that the standard solution employed was kindly furnished us by Dr. Rountree.

Table 1 shows the results obtained in the pregnant women, from which it will be noted that it takes considerably longer for the drug to appear in the urine during normal pregnancy than in ordinary non-pregnant individuals; the average time elapsing being 14.6 minutes in the former as compared to five to ten minutes in the latter. We also observed decided variations in the different individuals, the shortest time of appearance being nine and the longest twenty-four minutes, but in no case did this appear to be dependent on a diminution in the amount of urine passed.

Moreover, in no instance was the total elimination during the first hour as great as that noted by Rountree and Geraghty as the lower limit of normal. In our series of cases the average percentage was 21.39 instead of 50, as in Rountree and Geraghty's normal non-pregnant subjects. We also noted a very marked variation in the different individuals, the extreme limits being 2.4 and 39 per cent. In the second hour the average percentage eliminated was slightly higher than the lower limit set by Rountree and Geraghty, being 26.54 per cent., with variations from 11.4 to 59.1 per cent. It would therefore appear that in normal pregnant women the rate of elimination is more rapid in the second than in the first hour, which is in marked contrast with the findings of Rountree and Geraghty, who demonstrated that normal non-pregnant individuals eliminated only one-half as much of the drug in the second as in the first hour. Some idea of the discrepancy between our results and theirs may be gained when we state that in seven of our twelve determinations the elimination was higher, in three approximately the same, and in only two lower in the second than in the first hour. Adding together the amount eliminated during the first and second hours, we find that the average was 47.93 per cent. with extremes of 13.8 and 65.7 per cent., while in only two instances did the total elimination fall within the limits established by Rountree and Geraghty in normal non-pregnant individuals.

TABLE 2.—RESULTS OF TEST IN PUERPERAL WOMEN

			First Hour		Second Hour			
Obst. No.	Date of injection.	Time of appearance —minutes.	Amt. urine excreted, cc.	Percentage drug eliminated.	Amt. urine excreted, cc.	Percentage drug eliminated.	Percentage drug eliminated in 2 hrs.	Day of puerperium.
4511	8/ 9/10	10	370	34.2	340	30.5	64.7	6
4483	8/ 6/10	13	240	20	110	28.2	48.2	7
4489	8/16/10	10	300	51.7	85	11.1	62.8	8
4485	8/ 2/10	10	145	49.6	240	27.3	76.9	9
4441	8/ 2/10	13	140	27.1	95	30.3	57.4	9
4498	8/ 6/10	9	440	29.5	120	25.0	54.5	9
4487	7/26/10	15	125	41.8	300	20.3	62.1	10
4486	7/26/10	9	100	22.4	240	32.4	54.8	10
4497	8/ 9/10	8	475	20.2	540	35.2	55.4	10
4501	8/ 5/10	8	460	34.5	115	29.1	63.6	11
4500	8/ 5/10	6	290	58	125	12.6	70.6	11
Average		10.0	280.46	35.56	210	25.63	61.0	
Highest		15	475	58.0	540	35.2	76.9	
Lowest		6	100	20.0	85	11.1	48.2	

Table 2 shows the results obtained in the eleven puerperal patients. *In this series the time elapsing before* the appearance of the drug in the urine was approximately the same as that observed by Rountree and Geraghty in normal non-obstetric subjects. Moreover, the amount eliminated during the first hour approaches that observed by them, although the average elimination of 35.36 per cent. is considerably below their lower limit. In our series the high and low limits were 20 and 58 per cent. respectively, and in only four instances did the readings approximate Rountree and Geraghty's normal limits. In the second hour the average elimination was 25.63 per cent., which is slightly higher than the maximum noted by the above authors. In seven of our cases the elimination was greater, in two less, and in only two equal to their normal average. Although in our puerperal series the average percentage eliminated is greater in the first than in the second hour, the relative difference is not so great as is observed in non-obstetrical patients, and in several instances the figures for the second hour are higher than for the first. At the same time the total amount eliminated corresponds fairly well with Rountree and Geraghty's normal low limit, as the average was 61.0 per cent. with extremes of 48.2 and 76.9 per cent., while in six instances the readings fell within their normal limits.

Comparison of the results obtained in these two series of cases seems to indicate that several important points of difference exist in the renal activity of pregnant and puerperal women, which may be summarized as follows:

1. The average time elapsing before the appearance of the drug is shorter in the puerperium than in pregnancy, thus indicating diminished renal activity in the latter state. 2. In puerperal women the average amount of drug eliminated in the first hour is greater than in pregnant women, while in the second hour it is approximately identical in both groups. 3. The average total elimination is greater in the puerperium than in pregnancy. This is well exemplified in Table 3, which shows the results obtained in five women whose urine was examined both before and after delivery, and forcibly accentuates these points.

TABLE 3.—RESULTS OF TEST BOTH BEFORE AND AFTER DELIVERY

	—Pregnancy—			—Puerperium—		
Obst. No.	First Hour Percentage	Second Hour Percentage	Total Percentage	First Hour Percentage	Second Hour Percentage	Total Percentage
4484	39.0	18.5	57.5	49.6	27.3	76.9
4497	24.3	32.2	56.5	20.2	35.2	55.4
4411	25.2	24.3	49.5	27.1	30.3	57.4
4489	12.7	23.3	36.0	51.7	11.1	62.8
4498	32.6	27.0	59.6	29.5	25.0	54.5
Average	26.76	25.06	51.82	35.62	25.78	61.4

Notwithstanding the small number of cases studied, we consider that our findings show that pregnant and puerperal women react so differently to the phenolsulphonephthalein test, as compared with other non-pregnant individuals, as to indicate the existence of some radical change in the functional activity of the kidneys in the former. This being the case, great caution should be exercised in drawing conclusions from this test in toxemic conditions. We regret that we are unable to make definite statements in this regard. Unfortunately, neither of us, for the present at least, will be able to continue the work, but at the same time we feel that the results already obtained are sufficiently interesting to justify publication.

CONCLUSIONS

As the result of our investigations we feel that the following conclusions may be tentatively drawn:

1. Normal obstetrical patients eliminate phenolsulphonephthalein more slowly than normal non-pregnant individuals. Whether this is connected with the ordinary changes in metabolism observed at that time or is due to some other factor, we are at present unable to state.
2. In the last month of normal pregnancy the power to eliminate this drug may be very low, and falls far below the limits set for non-pregnant individuals.
3. Until more extensive observations are at hand we feel that this test should be applied with great caution in toxemic cases, although it is possible that further study will show that it may afford valuable diagnostic and prognostic information.

OBSTRUCTION OF BOWEL—DIETL'S CRISIS

REXWALD BROWN, M.D.

SANTA BARBARA, CALIF.

Patient.—Early Dec. 14, 1909, I was called to see Mrs. H. W. B. During the previous evening she had been stricken with intense abdominal pain, of sudden onset, the pain continuing with increasingly severe crampy exacerbations at intervals until I saw her. She had vomited twice within six hours.

Examination.—This revealed an extremely tender lump to the right of umbilicus. It was hard and seemed about the size of a tangerine orange. The patient said that the lump had appeared within the last two hours, and she was positive such condition had never existed before. The right rectus was very rigid and the right lumbar region was also on guard and sensitive. Bowels had moved previous to onset of pain, but not since. Pulse was 106, and weak volume, temperature 98.8 F. There were no urinary symptoms. The patient was frail, and had been a partial invalid for many years, suffering from a chronic phthisis pulmonalis. She had been under care of various physicians for abdominal and pelvic ailments, which at operation was found to be a general enteroptosis. The patient was hurried to Cottage Hospital and operation performed at once.

Operation.—Incision was made through the right rectus muscle. On entering the abdominal cavity the right kidney much enlarged and highly congested, presented through the opening. The kidney was displaced downward, rotated on a longitudinal axis through the mesonephron—the upper pole lay not far from the umbilicus—and was firmly bound along its whole length by old organic adhesions to the ascending colon and hepatic flexure. The ascending colon proximal to the hepatic flexure, was greatly distended and bluish black in color, the circulation was poor. The hepatic flexure was dragged on, stretched, compressed rotated and angulated, producing a mechanical obstruction of the bowel. The adhesions between the kidney and the hepatic flexure were severed, the obstruction was relieved and the kidney forced back as high as possible toward its normal bed. The patient's condition on the table was not good, and no attempt was made to anchor the kidney.

Postoperative History.—Convalescence was stormy, an immediate bronchopneumonia developed, and within two or three days appeared the phenomena of general septic invasion: chills, rapid pulse, and alternating high and subnormal temperature. Life was in the balance for two weeks and then convalescence ensued. Patient died five months later from the phthisis, there being no abdominal symptoms in the interval.

Strangulation ileus due to bands of adhesions is not a rare condition, however, in a short search of the available literature I am unable to find a case in which the twisting of a kidney pedicle—Dietl's crisis—has been a factor in causing adhesions to close bowel lumen and blood-current.

AN EXTRACEREBELLAR TUMOR

EDWARD L. MOORHEAD, A.M., M.D.

CHICAGO

Extracerebellar tumors lie in the cerebello-pontine recess. They apparently arise from the acoustic nerve; usually grow slowly and it may be years before symptoms, produced by pressure on the lateral lobe of cerebellum and pons, to which they are adherent, appear.

This case was referred to me May 23, 1910:

History.—Mr. R. W., aged 58, married, a car repairer, born in Switzerland, had lived in America thirty years. His health had always been good. There was no specific history. Two years ago he had a discharge from the right ear which continued for about two weeks. He began to complain of deafness in the left ear about three years ago. Two years ago, he was struck under the right eye by a jack-handle, causing some swelling and discoloration. In February, 1910, he began to complain of being dizzy when he would stoop over. There was headache and a sense of fulness across the frontal region. The dizziness increased and late in April, 1910, he noticed that he began to stagger, the tendency being toward the left side.

Examination.—This revealed marked ataxia of cerebellar type, with tendency to fall to the left, left nerve deafness, partial right deafness (middle ear), slight weakness of left facial nerve, including upper branch; taste not involved; left corneal reflex absent, but no other evidence of fifth nerve involvement; no ocular paralysis. Tendon reflexes were slightly increased on both sides; there was no clonus; no Babinski sign; no sign of paresis of opposite side of body; no optic neuritis, but veins of disks rather full. In the examination of patient I was assisted by Dr. T. Faith, oculist; Dr. H. Kahn, aurist, and Dr. P. Bassoe, neurologist.

Diagnosis.—Tumor at left cerebello-pontine angle, probably a fibroma of the auditory nerve (left-sided deafness preceded vertigo by two or three years), but primary growth in cerebellum or pons, with pressure on auditory and facial nerves possible. At any rate, the growth was subtentorial and on the left side.

Treatment.—While there was nothing in the patient's history, or found on examination, to point to a syphilitic origin of the disease, yet it was thought advisable to put him on specific treatment for a time. He remained in the hospital for two weeks and then returned to his home. The treatment was pushed vigorously until July 4, a period of six weeks, without any effect, the patient growing worse, being now unable to walk without falling, unless assisted.

The patient and his family requested that I operate on him in the hope of obtaining some relief. He was readmitted to the hospital July 4 and prepared for operation.

Operation.—July 6 under ether anesthesia, the usual horseshoe-shaped incision was made through the soft parts. The skull was opened with Hudson trephine and the opening enlarged by Dahlgren forceps. No growth was found in the cerebellum, but high up, above the root of the cerebellum a dense mass was felt. As it was firmly attached to the pons, it could not be removed or brought into view. The wound was closed without drainage. During operation the anesthetic caused some trouble, the patient taking it badly.

The patient reacted from operation, but on the third day developed pneumonia, resulting in death the fourth day.

Necropsy Findings.—The specimen removed at the autopsy shows a fibroma about 3 cm. in its longest diameter and 2.5 cm. in its transverse diameter. It was firmly adherent to the side of the pons, its origin apparently being from the auditory nerve.

Therapeutics

THE THYROID

(Continued from page 1983)

PATHOLOGY OF THE THYROID GLAND

1. The thyroid normally varies in size and in the amount of its secretion with age, sex, locality, and condition; the variations being greater in women than in men.

2. It may be inflamed, or there may be actual abscess formation.

3. It may be enlarged: (*a*) by an increase of the glandular tissue (hypertrophy); (*b*) by an increase of the colloid deposit; (*c*) by the formation of cysts; (*d*) by a dilatation of the blood-vessels, even to aneurysmal sacs; (*e*) by connective tissue development; (*f*) by tumor growth (sarcoma, cancer).

4. It may be decreased in size: (*a*) by connective tissue displacement of the glandular tissue—a sclerosis; (*b*) by general atrophy.

5. The gland may be large, and yet under-secrete.

6. The gland may be apparently small, and yet secrete sufficiently, and even hypersecrete.

Thyroid Congestion.—The thyroid probably becomes congested and stimulated with every infection, and Lorand, of Vienna (*Lancet*, London, Nov. 9, 1907) states his belief that the thyroid is an active agent in antagonizing all infections, and that when it is so stimulated, it is one cause of fever and the symptoms of fever, such as thirst, high temperature, sweating, nitrogenous loss, and wasting of the body. He believes that the thyroid is an active agent in fighting tuberculosis, and thinks that after a patient has gone through serious illnesses, or when some chronic depressing disease is present, the thyroid becomes worn out, and that is the time when tuberculosis readily attacks or develops in the patient. Whether or not we accept his conclusions as to the cause, the sequence is certainly a fact, that tuberculosis readily develops after typhoid fever, prolonged infection, prolonged alcoholism, after parturition, after prolonged lactation, and during diabetes. If his conclusions are correct, thyroid in small doses would be indicated in *tuberculosis*. But if the heart is rapid, as it generally is in this disease, thyroid should be given with care. Whether the iodin of thyroid extract would be a stimulant to the tuberculous process, as is an iodid, is a question that has not yet been decided. An iodid in active tuberculosis or in quiescent tuberculosis is more or less vicious in its action, sometimes stimulating the tuberculous process to activity, much as would tuberculin. In other words, an iodid should probably never be used in tuberculosis, especially of the lungs.

It seems to be a fact that after cured tuberculosis and after typhoid fever, diphtheria, and other serious infections, the thyroid tends to develop a greater amount of connective tissue, even if the glandular tissue does not actually atrophy. This may be one of the reasons that after severe infections arteriosclerosis is likely to occur earlier than in patients who have not suffered these illnesses, insufficient thyroid secretion tending to cause arteriosclerosis. Although congestion of the thyroid frequently occurs with infection or illness, active inflammation is rare, but it is more frequent than once thought. Actual suppuration is exceedingly rare.

Thyroid Hypertrophy.—Ordinarily, when the glandular tissue is hypertrophied, it is hypersecreting; and this may be on account of some necessary function of the body, as menstruation or pregnancy. If there is no such necessity for its hypertrophy and hypersecretion, abnormal symptoms occur, and if the condition progresses, exophthalmic goiter is the result. With this hypertrophy the blood-vessels are always enlarged and may become dilated to a condition of aneurysm. Aneurysm of a thyroid artery may be present without an increased glandular activity of the gland, but the two conditions are generally concomitant.

Increased colloid deposits and the formation of cysts produce an ordinary goiter; *i. e.*, an enlarged thyroid gland is present, but with no signs of its hypersecretion. An enlargement of the thyroid from connective tissue deposit sooner or later means under-secretion of the gland and symptoms indicative of hyposecretion.

If a tumor growth, like sarcoma or cancer, begins in some portion of the thyroid, the part of the gland not affected often becomes irritated to hypersecretion, so that symptoms from such increased secretion may be present as the tumor continues to grow. This is not always the case.

Thyroid Atrophy.—The thyroid normally atrophies after 45, and gradually developing symptoms of insufficient secretion occur. Premature shrinking of the gland may occur from connective tissue displacement of glandular tissue, a sclerosis, as above stated, from prolonged serious infections. If it is atrophied or its secretion is insufficient at or soon after birth, the child is a cretin. If it only partially secretes, with a probable disturbance of the pituitary gland (hypophysis cerebri), the child may grow large, but shows infantile obesity. If the gland ceases its secretion during adult life, or if the gland is removed by operation, myxedema is the result.

Thyroid Secretion.—The fact that a gland is palpable and large is no positive assurance that it is properly secreting. The symptoms which the patient gives and the signs which are found will determine whether its secretion is sufficient.

Occasionally a small thyroid gland is found and yet symptoms of hypersecretion are present. This, however, is a rarer condition than that of an enlargement and under-secretion.

STIMULANTS OF THE THYROID GLAND

Nervous tension, great sorrow, great joy, sexual excitement, genital disturbances (especially uterine), pregnancy, meat, coffee, tea, alcohol, arsenic, iodids, phosphorus, salicylic acid, pilocarpin, and, greatest of all stimulants, thyroid extract.

The hypersusceptibility of some patients to iodids, the so-called idiosyncrasy to these drugs, probably means that their thyroids are hypersusceptible to such stimulation. This susceptibility is most likely to occur in neurotic families.

DEPRESSANTS OF THE THYROID GLAND

Quiet, seclusion, rest, absence of all sexual excitation and all genital irritation, milk and cereal diet, glycerophosphates of lime and soda and perhaps all forms of calcium, opium in any form, ergot, bromids, chloral, and perhaps most hypnotics.

HYPERSECRETION

When the chemical analysis of the thyroid gland has reached perfection it will doubtless be found that although the histologic structure of the gland may seem normal, the secretions which it furnishes will be proved to vary greatly, both as to the amounts of the various elements and perhaps in their chemical structure. In other words, it will doubtless be found chemically, as we know clinically, that there are wide variations from the excessive secretion of all elements, as occurs in Graves' disease, to the diminished secretion of all elements, as occurs in myxedema, and that all of these variations from normal to the upper limit or Graves' disease, or from normal to the lower limit or myxedema, produce symptoms, the former from hypersecretion of some elements and the latter from hyposecretion of some elements.

The frequency with which the normal thyroid increases its activity in women, and the tendency in them for the gland to recede not rapidly to normal activity, is the cause of their excitable, nervous, and hysterical natures, and is also the reason that the final result of hypersecretion, Graves' disease, occurs four times as frequently in women as in men. The opposite is also true (as is so true of every glandular activity), *viz.*, that this gland is more likely to wear out, atrophy and hyposecrete in women after 45 than in men, and in the same ratio, 4 to 1.

There is a condition recognized as *thyroid instability*, *i. e.*, there are at one time symptoms of hypersecretion, and at another time symptoms of hyposecretion, or the secretion of the gland may be apparently normal, and there may occur crises of hypersecretion or disturbed secretion. Symptoms of this condition are evidenced by unexplainable and otherwise inexcusable asthmatic attacks, urticarial attacks, eczematous eruptions, diarrheas, subacute rheumatic attacks, unexplainable vomiting, and, perhaps, attacks of migraine, to say nothing of attacks of tachycardia. While many of these conditions may be otherwise explained, instances occur in neurotic patients when no one condition other than disturbance of the thyroid could cause so many apparently serious but self-limited conditions. The least that can be said is that such unexplained attacks should be studied from the standpoint of disturbance of the thyroid.

The evident conditions caused by hypersecretion are: (1) menstrual disturbances; (2) hysteria; (3) tachycardia; (4) symptoms of the menopause; (5) Graves' disease; (6) puerperal insanity; (7) acute mania.

1. The *profuse menstruation* of young girls is generally due to excessive activity of the thyroid gland, whereas its underactivity causes amenorrhea and chlorosis. Such girls with undersecretion or disturbed secretion may have peculiar nervous crises, perhaps even epileptic attacks, and the case is on record of one patient who was cataleptic. Women may also have profuse menstruation from too much thyroid secretion. The thyroid is also often at fault (*i. e.*, hypersecreting) when menstruation occurs too frequently, as every three or even every two weeks. This is especially true in young girls. The best treatment for this profuse menstruation or *menorrhagia*, when there is no apparent uterine reason, and also for this too frequent menstruation, is mammary extract, in tablet, to be crushed by the teeth and taken in doses of from 3 to 5 grains, three or four times a day. It is partially efficient in shortening a prolonged menstrual flow (its administration is best begun on the third day), but its best action is when administered during the interim between the periods. It will often postpone the period to the normal time, and prevent the flow from being profuse.

2. *Hysteria* has never yet been definitely defined. There has never been a lesion found; the condition has never been explained. What better etiology do we require to explain the manifold manifestations of hysteria than in disturbance of this emotional gland? Most hysterical symptoms are due to overactivity or disturbed activity of the gland, and it is perfectly natural that this gland, which is over-acting so many more times in women than in men, should cause them to be the ones most frequently to suffer from hysteria. It is hardly necessary to enumerate the hysterical manifestations to see how closely they coincide with known symptoms of thyroid hyperactivity. The crying, the laughing, the flushing, the sweating, the rapid heart, the pains without reason, and even the hysterical fever can all be accounted for by reference to the thyroid. The opposite, hysterical indifference, apathy, slow heart, hysterical moroseness, and even hysteroepilepsy, may be accounted for by subsecretion, or hyposecretion, of the thyroid.

3. It is merely begging the question to entitle a condition in a text-book as tachycardia, and yet this has been done for years. *Tachycardia* without a cardiac lesion or cardiac excuse, occurring often on least excitation, as after a cup of coffee or a glass of wine, or after mental excitation or any sudden nervous disturbance, or after any other intangible reason for rapid heart action, a paroxysmal misbehavior of the heart (not permanent, as occurs in Graves' disease), is undoubtedly

due to thyroid hyperactivity. Anything that will quiet the thyroid will stop the tachycardia. Of course such tachycardias tend soon to stop without treatment.

4. The so-called *menopause* symptoms are simply those of thyroid activity. They will be present in modified form or entirely absent if the menstruation ceases gradually and the thyroid thus gradually ceases its periodic hyperactivity. If the menstruation ceases rather abruptly, or there are long abrupt periods of intermittency, the thyroid persists in its cyclic hypertrophy and hyperactivity, and with the inability of the blood to rid itself of extra thyroid secretion by bleeding, the woman becomes intoxicated with the thyroid and develops symptoms, such as hot flashes, sweatings, palpitations, nervous irritability, restlessness, and perhaps actual hysteria. She may be relieved by bleeding from the nose, by diarrheas, polyuria, or in some other way, but she is miserable for several or more days until the period of the activity has passed. Little by little the gland will normally lessen its activity, and these symptoms disappear. If she again menstruates the relief which she gets is absolute until the next or permanent stoppage of menstruation. She will pass through this same condition if, for any reason, both ovaries are removed. Fortunately, this is now rarely done, as it has been learned that even a small piece of an ovary will functionate and prevent operative menopause. Any of the conditions or drugs named under those that tend to inhibit secretion of the thyroid are of value. Perhaps the drug of greatest value at this period is a bromid. Patients, however, having these uncomfortable menopause symptoms should be treated much on the plan of a mild Graves' disease.

The above symptoms of the menopause are very frequent and very constant, but that the symptoms of the menopause are due to a hyperactivity of the thyroid, is a fact even yet recognized by but few as the cause of the condition. Rarely the thyroid ceases its activity abruptly, or at least too greatly under-secretes soon after the menopause. Such patients rapidly put on weight, and, if the secretion is too greatly diminished, develop myxedema. Myxedema has been recognized for years as due to subcretion of the thyroid. Most women and many men put on weight after the age of 45, owing to a diminished thyroid secretion.

5. Graves' disease will be treated in the next article on thyroid.

6. The cause of *puerperal insanity* has not been explained. It is probable that this is due to a disturbed thyroid, and probably to a hypersecretion. During pregnancy the thyroid is hypersecreting, or at least should be hypersecreting, to care for the double metabolism of mother and fetus. If it is insufficient, symptoms occur, and if much insufficient, it may be a cause of puerperal eclampsia. That its increased secretion is utilized is shown by the fact that if a woman who is suffering from Graves' disease becomes pregnant she often suffers no symptoms of thyroidism during the pregnancy, but frequently the symptoms again occur after the pregnancy has terminated. However, it should be emphasized that a woman who has Graves' thyroid disease should not marry. From deductive reasoning, then, it would seem probable that puerperal insanity is due to abnormal activity of the thyroid.

7. There are certain forms of *acute mania* occurring as an intoxication, the causes of which have not yet been explained. It is possible that excessive thyroid secretion or disturbed thyroid secretion is the cause.

(To be continued)

GOOD SENSE IN PRESCRIBING

℞ Gm.
Digitalis ....
Quininæ sulphat āā .... 0.05 (gr. 1)
Extract gentianæ q. s. ut ft. pilula, d. tal. dos. No. xx.
Sig.: One or two pills three times daily.

It makes no difference whether Skoda (the alleged author of this pill) or some other man of equal or greater note first wrote or recommended this combination. It is not good sense. In the first place, the amounts in the prescription should be distinctly ordered by the prescriber, and then the amount divided into as many pills or capsules as the physician desires. The exact dose is thus supervised by both the physician and the pharmacist. In the above prescription there is only one to supervise the dose, and that is the pharmacist; in other words, he multiplies the dose by 20, and has no supervisor as to whether or not he makes a mistake.

In the next place, the amount of Latin required to write this prescription correctly, even with everything abbreviated, is unnecessary and uncalled for. If 1 gram (15 grains) of each of the active ingredients is ordered, and then the pharmacist is ordered to make 20 pills, the whole prescription is much simpler. The amount of the extract of gentian is entirely left to the decision of the pharmacist; in other words, it is not used at all as a drug, but is simply used as an excipient with which to make up the dry powders into pills. Why specify a pharmacopeial preparation for such a simple thing as an excipient? Whatever amount of gentian was used as the extract would be of no tonic value under any circumstances. Therefore, the excipient had much better be left to the pharmacist, if a pill is to be made.

It is always uncertain just when a pill of this description will dissolve and how much of the 0.05 gram of digitalis will ever give up its activity. If it is advisable to give digitalis in powdered form with quinin, how much better to order these two dry drugs placed dry in a capsule; then, as soon as the gelatin dissolves the powder is ready for chemical combinations and absorption.

The playing with strong drugs is inadvisable; digitalis leaves in dry powder and of uncertain strength combined in a sticky pill for slow disintegration and absorption is very uncertain, and if digitalis is actually needed, is too uncertain for scientific use. On the other hand, if digitalis is not needed, it is wrong to use a strong drug thus carelessly. With such a prescription, then, the patient gets better because of the other orders and his general management, and the prescription plays but a small part in the effect, except that on his mind. This of course is very valuable, but, if analyzed, it brings the physician into ridicule from the intelligent mental curist who knows that it is the general management and the impression on the mind rather than the prescription that did the work. If a prescription is to be written or a drug given for impression on the mind, let it not carry with it the uncertain activity of poisonous drugs.

The quinin in this prescription may become a tonic because, if enough of it is absorbed, it is more or less excreted by the saliva, and at the following meal food and drinks taste slightly bitter, and such a bitter is an appetizer. Also, quinin is a stimulant to the nervous system. The above dose of course is very small.

To sum up, if digitalis is needed it had better be administered in liquid form. If it is not needed, it should not be used at all. The extract of gentian plays no part in the therapeutic story. The small dose of quinin may be advisable in pill, tablet, or capsule.

ERGOT

Some splendid work on this drug has recently been completed by Dr. Horatio C. Wood, Jr., and Dr. Clarence A. Hofer, of Philadelphia. Their results and the tables of their experiments are published in the *Archives of Internal Medicine,* (October, 1910, p. 388).

It is a pleasure to note that they have pharmacologically determined what has been urged by a few men clinically, that ergot causes vasocontraction of the arteries and is probably a stimulant to the heart. In other words, ergot raises the blood-pressure and is of benefit to the heart. These investigators show that the action on the blood-vessels is due to peripheral action on the muscles in the blood-vessel walls, and not to action on the vasomotor center. They also show that the increase in blood-pressure caused by the drug is an accurate indicator of the activity of the ergot employed, and that the amount of the active principle of the drug, sphacelotoxin (a chemical union of the alkaloidal substance of the drug *hydro-ergotinin* with a resinous body) is also indicated by the rise in blood-pressure. Ergot is also a stimulant to all of the unstriped muscle tissue of the body.

Wood and Hofer also positively prove that the ergot on the market varies greatly in its active principle, *i. e.*, in its power to cause unstriped muscle stimulation. They also show that a perfectly prepared fluidextract rapidly and continuously loses its activity and becomes worthless. The crude drug also loses its activity on keeping. Therefore, they come to the conclusion that all liquid preparations of ergot should be kept in small bottles, hermetically sealed, and even then they think that the label should declare at what date it is manufactured, since, if a preparation is old, it is of but little value. Ordinary fluidextracts, even if not exposed to the air, will lose approximately 10 per cent. of their strength per month; hence the ordinary fluidextract on the market, bottles of which are frequently opened, lose their strength much more rapidly, and are really generally worthless.

Vaccine Therapy in Otology.—H. O. Reik in the *Laryngoscope* states that the employment of vaccine therapy in otology, although having had but a limited trial so far, has been attended by such successful results as to warrant us in feeling greatly encouraged. Furunculosis, with its recognized tendency to the formation of boils in crops, seems to have responded more promptly and satisfactorily to this form of treatment than to any other, and, in tuberculosis of the middle-ear, a condition heretofore so baffling to the otologist, there would seem to be a good reason to believe that at last we have a controlling, curative remedy. Looking into the future, there has been held out to us the enticing prospect of being able to cure without operation a larger percentage of patients with persistent chronic, purulent otitis media, or, failing in that, of insuring success for operative treatment of this affection. The aural conditions to which this new form of treatment would appear to be reasonably applicable are, Reik says, the treatment of chronic suppurative otitis media; the preparation of patients for operation, raising the opsonic index in order to facilitate rapid healing after obliteration of the gross lesions, and the postoperative treatment of mastoiditis and its complications, when healing is delayed and the patient is unable to construct new tissue without aid. While the outlook is hopeful in these several directions, we must not grow too enthusiastic as yet. We are perhaps justified in some degree of optimism but not in enthusiasm. Let us try the method further, with fairness and judiciously, Reik urges, not expecting the impossible of it, for it will not entirely displace any other form of treatment; no matter how valuable it ultimately becomes, it will only be an additional therapeutic measure at our command.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

[For list of articles which have already been mentioned in detail, see THE JOURNAL, page 1980, last week.]

ARBUTIN.—Arbutinum.—Arbutin, $C_{12}H_{16}O_7 + \frac{1}{2}H_2O$, is a glucosid occurring in the leaves of *Arctostaphylos Uva-ursi* Spr., *Vaccinium Vitis-Idaea L.* and many other genera of the family *Ericaceae*.

Arbutin occurs in long, glistening, colorless needles, or as a fine, white, crystalline, odorless powder having a bitter taste. It is soluble in 8 parts of water and 16 parts of alcohol; very soluble in hot water and hot alcohol; insoluble in chloroform, ether and carbon disulphid. Its aqueous solution is neutral to litmus paper and is not precipitated by solutions of the metallic salts or by solution of tannin. Its aqueous solution is colored blue by ferric chlorid test solution. By boiling with diluted sulphuric acid or by treatment with emulsin arbutin is converted into glucose and hydroquinone.

When heated to 100° C. (212° F.) arbutin loses its water of hydration. At 144° to 146° C. (291.2° to 294.8° F.) the anhydrous glucosid melts. It should leave no residue on ignition.

An aqueous solution of arbutin (1/20) should not be affected by hydrogen sulphid (absence of lead).

Actions and Uses.—Arbutin probably owes its effect, at least in part, to the antiseptic action of hydroquinone, formed by its decomposition in the urinary tract. It has been used as a urinary antiseptic and diuretic.

Dosage.—0.2 to 0.5 Gm. (2 to 7 grains) three or four times a day.

NUCLEIC ACID.—Acidium Nucleicum.—Nucleinic Acid.—Nucleic acid is an organic acid obtained from nuclein by the action of alkalies or by tryptic digestion.

Nucleic acid is an amorphous, white powder and has an acid reaction. It is readily soluble in ammoniacal or alkaline water with the formation of water-soluble salts. From these solutions it is precipitated by slight excess of hydrochloric acid but not by acetic acid. It is insoluble in alcohol and ether. When chemically pure it does not give the biuret test or Millon's reaction, but a slight response to these reagents does not indicate a degree of impurity incompatible with its use as a medicinal agent.

It should contain between 14.5 and 16.5 per cent. of nitrogen and between 8.5 and 10.5 per cent. of phosphorus, the relative proportion being 4 atoms of P to 14 or 16 N, approximately.

Actions and Uses.—See Nuclein, Nucleic Acid and Nucleates.

Dosage.—0.06 to 0.3 Gm. (1 to 5 grains) three times a day.

Non-Proprietary Preparation:

Nucleinic Acid Merck (from Yeast).—Manufactured by E. Merck, Darmstadt, Germany (Merck & Co., New York).

ACNE VACCINE—A vaccine prepared from acne bacilli (Bacillus acnes). Said to be useful in the milder forms of acne.

H. K. Mulford Co., Philadelphia.

Acne-Bacterin. This product is marketed in four syringes containing respectively 25 million, 50 million, 100 million and 200 million killed acne bacilli, sold in a package or as separate syringes.

Dose. Initially 5 to 25 millions.

FRIEDLANDER VACCINE.—A vaccine prepared from the Friedlander bacillus. It is said to be useful in infections by the Friedlander bacillus, such as chronic nasal catarrh and chronic gleet.

H. K. Mulford Co., Philadelphia.

Friedlander Bacterin. This product is marketed in packages of four syringes, containing respectively 50 million, 100 million, 200 million and 400 million killed Friedlander bacilli. The single syringes may be obtained separately.

NORMAL HORSE SERUM.—(See N. N. R., p. 186).

H. K. Mulford Co., Philadelphia.

Normal Serum (From the Horse). Marketed in packages of two syringes, each containing 10 Cc.

ANTIMENINGOCOCCUS SERUM.—(See N. N. R., p. 172).

H. K. Mulford Co., Philadelphia.

Antimeningitis Serum. A serum prepared from the blood of horses immunized to the meningococcus of Weichselbaum (Diplococcus intracellularis), according to the method of Flexner (inoculation of autolyzed cultures followed by living organisms).

It is useful for the treatment of epidemic cerebrospinal meningitis, due to the meningococcus.

Dose. 15 to 30 Cc. (4 to 8 fluidrams) given by intraspinal injection For young infants, 10 Cc. (2½ fluidrams). The serum is marketed in aseptic glass syringes with sterilized needle.

STAPHYLOCOCCUS VACCINES.—(See N. N. R., p. 179).

H. K. Mulford Co., Philadelphia.

Four varieties of vaccine are offered:

1. *Staphylo-Albus Bacterin.* From staphylococcus pyogenes albus.
2. *Staphylo-Aureus Bacterin.* From Staphylococcus pyogenes aureus.
3. *Staphylo-Bacterin.* Containing a mixed culture of staphylococcus albus, aureus, and citreus.
4. *Staphylo-Acne-Bacterin.* A mixed vaccine prepared from cultures of staphylococcus albus, aureus, and citreus with bacillus acnes.

All the above are marketed in packages of four syringes containing respectively 250 million, 500 million, 1 billion and 2 billion killed staphylococci. The syringes of staphylo-acne bacterin contain in addition, respectively, 25 million, 50 million, 100 million and 200 million acne bacilli. The single syringes may be obtained separately.

TUBERCULOSIS SERUM VACCINE.—An emulsion of human tubercle bacilli, sensitized by the application of tuberculosis serum.

> The production of sensitized tubercle bacilli, or bacilli which are capable of complement fixation, is accomplished with the assistance of an efficient tuberculosis-immune serum, which has a considerable content of specific amboceptor antituberculin. The content of this serum in specific amboceptor is ascertained according to the method of complement fixation. Besides antituberculin, this serum contains agglutinating, precipitating and bacteriotrope immune bodies.
>
> Emulsions of sensitized tubercle bacilli are prepared as follows: Human tubercle bacilli, after having been thoroughly washed and briskly dried, are mixed with fresh tuberculosis serum, the quantity of which is calculated from the determination of the immunity bodies. This mixture is left for several days in the incubator, at a temperature of 37° C., and is then shaken in an apparatus, with glass beads, until intact tubercle bacilli are no longer demonstrable in the removed sample. The broken-up masses of bacilli are then separated from the serum, through centrifugalization, washed with physiologic salt solution, and finally worked into fine emulsions, with 40 per cent. glycerin water, to which has been added phenol 0.5 per cent. The contents of this emulsion in bacilliary substance amounts to 0.005 Gm. in 1 Cc. The original emulsions and dilutions are to all intents and purposes permanently durable, provided they are kept in a cool place, not exposed to freezing, and protected from the light.

Actions and Uses.—It is claimed that this emulsion contains specific immune bodies which are non-poisonous for healthy and tuberculous subjects, but are capable of exerting a remarkable effect on tuberculous processes.

Farbwerke vorm. Meister Lucius and Bruening, Hoechst, a. M., Germany. (Victor Koechl & Co., New York.)

Tuberculin "Koch" (old). Marketed in vials containing 1 Cc., 5 Cc. or 50 Cc.

New Tuberculin "Koch" (T. R.). Marketed in vials containing 1 Cc. and 5 Cc.

Koch's Bacilli Emulsion. Marketed in vials containing 1 Cc. and 5 Cc.

Tuberculosis Diagnostic "Hoechst." Dried tuberculin free from glycerin, prepared from Tuberculin Koch (old Tuberculin). To be used in 0.1 per cent. solutions for the tuberculo-ophthalmic reaction.

Tuberculosis Diagnostic "Hoechst" Dry in Tubes. Each tube contains 0.005 Gm. (1/10 grain).

Dosage. The contents of a tube are dissolved in 5 Cc. of cold sterile water.

Tuberculosis Diagnostic "Hoechst" 0.1 per cent. solution.

Dosage. The contents of the tube are ready for use.

Tuberculin T. O. A. Original Tuberculin T. O. A. This preparation is a bouillon filtrate. For preparation see Tuberculin "Deny's," N. N. R., p. 181. Supplied in bottles containing 1 Cc. and 5 Cc.

Vacuum Tuberculin. Tuberculin T. O. A. reduced to 1/10 of its volume in a partial vacuum at a low temperature.

Actions and Uses. It is intended solely for the treatment of patients who exhibit too violent reactions to Old Tuberculin, to Tuberculin T. R. and to Tuberculin Bacilli Emulsion.

Vacuum Tuberculin is marketed in glass bottles containing 1 Cc. and 5 Cc.

Dry Dead Tubercle Germs. For use in making the bacillary emulsion for the tuberculo-opsonic test.

Bovine Tuberculin. Tuberculin corresponding to Tuberculin "Koch" Old but prepared from bovine bacilli. Marketed in bottles containing 1 Cc or 5 Cc.

Bovine Bacilli Emulsion Corresponding to Koch's Bacilli Emulsion but prepared from bovine bacilli. In original bottles containing 1 Cc. and 5 Cc.

Bovine Tuberculin T. R. Corresponding to Tuberculin T. R. but prepared from bovine bacilli. In bottles containing 1 Cc.

Bovine Tuberculin Old. A bouillon filtrate from bovine bacilli. Indications similar to those for Tuberculin T. O. A. Supplied in glass bottles containing 1 Cc. and 5 Cc.

Vacuum Bovine Tuberculin. A tuberculin prepared from bovine bacilli by the process for vacuum tuberculin. The advantage of the vacuum preparations is only in their better keeping qualities. Vacuum bovine tuberculin is supplied in glass bottles containing 1 Cc. and 5 Cc.

Polygenous Tubercle Bacilli Emulsion. A bacilli emulsion prepared from eight different cultures of tubercle bacilli which differ as much as possible from each other.

Dead Bovine Tubercle Bacilli. Supplied in flasks containing 1 Gm. and 5 Gm.

Tuberculin Residue. Tuberculin residue is supplied in the form of a moist paste and a dry preparation in vials of 1 Gm. and 5 Gm. each.

Tuberculosis Serum Vaccine "Hoechst." Emulsions of sensitized tubercle bacilli are supplied in the original concentration, in vials of 1 and 5 Cc. each, and also in serial dilutions.

Dosage. The treatment is begun with 0.1 Cc. of a dilution 1/1,000,000 and the dose gradually increased until 0.5 Cc. of the original emulsions are readily tolerated and the corresponding clinical effects are demonstrable. It should not be used in the presence of cachexia, mixed infection or permanent rise of temperature.

Tuberculin Gesellschaft, St. Petersburg, Russia. (Morgenstern & Co., New York.)

Endotin.—Tuberculinum Purum. Endotin is the purified extract of a filtered culture of human bacilli in 50 per cent. glycerin.

Endotin is prepared exactly as Koch's "Old" tuberculin, but is subsequently treated with alcohol, ether, chloroform and xylol in order to eliminate the deuteroalbumoses present.

Tuberculinum purum is now supplied in a carton of 4 series which are intended to represent a course of tuberculin treatment. Each series consists of 7 ampuls.

Noguchi Test for Syphilis

Noguchi test for syphilis is a modification of the method of Wassermann and involves the use of two standardized papers as follows:

Amboceptor Paper.—This is obtained by injecting washed human blood corpuscles (erythrocytes) into rabbits, at intervals of five to seven days, over a period of five or six weeks. Ten days are allowed to elapse after the last injection. The rabbits are then bled and the serum collected. Filter paper is now saturated with this serum and allowed to dry. The paper is cut in strips and set aside until wanted for use. In this form amboceptor will keep for a considerable length of time.

Amboceptor paper is standardized by measuring its specific activity. The measurement of specific activity consists of finding the amount of amboceptor necessary to cause hemolysis in 1 Cc. of suspended human red corpuscles, one drop of blood in 4 Cc. normal saline solution with 0.02 Cc. of fresh guinea-pig serum. Incubate this at a temperature of 37½ C. for one hour. The quantity of paper necessary to cause hemolysis under these conditions is known as 1 unit.

Antigen Paper.—Antigen is made by rubbing liver tissue with sand and extracting with alcohol. One Gm. of liver tissue is macerated in 10 Cc. of alcohol for one week at 37.5 C., shaking the container every day. It is filtered until clear and the filtrate evaporated. The resulting extract is dissolved in ether and this solution poured into a large quantity of acetone. The acetone precipitates certain lipoid substances, which are then collected and redissolved in ether-alcohol and constitute the antigen. Antigen papers are now prepared by saturating filter paper with this solution and allowing it to dry, after which it is cut into strips. The unit of standardization is the amount of antigen paper necessary to prevent hemolysis of human red corpuscles in the presence of syphilitic serum. The antigen paper must not of itself cause hemolysis.

H. K. Mulford Co., Philadelphia.

Noguchi Test Mulford. Noguchi test Mulford consists of amboceptor paper and antigen paper in a package accompanied with full directions for use.

Amboceptor Paper. Amboceptor paper is marketed in a glass tube.

Antigen Paper. Antigen paper is marketed in tubes containing acetone, because it is believed to prevent oxidation. When wanted for use, a strip of the paper is removed from the vial and the acetone allowed to evaporate.

KOCH'S LAST WORD ON TUBERCULOSIS

Shortly before he died, Robert Koch delivered an interesting lecture in the Academy of Sciences in Berlin on the epidemiology of tuberculosis This lecture has now been published[1] In it Koch discusses certain statistics bearing on the death rate of pulmonary tuberculosis, or phthisis, which is the most favorable form of tuberculosis for statistical purposes

It appears that the first reliable statistics were gathered in Sweden and that in the middle of the eighteenth century the mortality in Sweden for the country was 21 5 per ten thousand of the living population and for Stockholm 73 2 The rate rose slowly and steadily far into the nineteenth century, owing, it was thought, to the abuse of alcohol

One of the most remarkable features in the epidemiology of tuberculosis is the lowered death-rate during more recent years, and it is to this phase that Koch directs especial attention At first the statistics showing decrease were received with skepticism, but as the decrease became more and more general, it became an accepted fact Koch gives curves showing that in Prussia a decrease commenced in 1886, which has been going on fairly regularly since, so that in 1908 the death rate had fallen 50 per cent The curve for the whole of Germany resembles very much that for Prussia If the conditions that obtained in Germany thirty years ago had continued up to the present, something like a hundred thousand human beings more per year would have died from pulmonary tuberculosis Consequently it becomes a matter of the greatest importance to discover, if possible the causes of the decrease with a view to favoring its rate and its continuance

As the death-rate of pulmonary tuberculosis falls more rapidly than the general death-rate, which is also decreasing, there must be factors at work that are peculiar for tuberculosis If the decrease depends on something inherent in the nature of tuberculosis so that the disease was bound to decrease of itself, then the decrease should take place in a uniform manner everywhere But this is not the case There are countries in which the disease has been increasing, notably Ireland, Norway, until very recently, and Japan In Paris the curve shows little tendency to go down It appears also that in New York and especially in Berlin the decrease has been less during the last few years than previously There are also difficulties in the way of explaining the fall in the mortality of pulmonary tuberculosis by any sudden loss in virulence of the disease

The fall in the death-rate of tuberculosis is often brought into relation with the discovery of the bacillus This established the transmissible character of the disease and naturally led to preventive measures Thus it is remarkable that with few exceptions the decrease begins almost everywhere within a few years after this discovery There are, however, exceptions to this connection Koch finds the conditions in Great Britain especially interesting. As is well known, the death-rate from tuberculosis is decreasing in England and Scotland and increasing, although slowly, in Ireland. Newsholme, who has studied this question with the greatest care and from all sides, reached the conclusion that the modes of caring for the tuberculous poor form the determining factor in England and Scotland they are cared for in institutions, whereas in Ireland they are not necessarily so cared for This was the case in Norway also until recently; since special institutions began to be established the death-rate has fallen In Paris also there is a lack of suitable hospitals Koch supports Newsholme, in no other way is the danger of infection from a phthisical patient so thoroughly avoided as by isolation in a hospital In leprosy we have a striking example of the preventive effect of isolation and hospital treatment

Koch then goes on to discuss the importance of the character of the living-rooms and more particularly the sleeping-rooms with respect to the spread of tuberculosis. In Germany the highest mortality is not in the poorest districts, but in relatively prosperous regions along the North Sea, where it is the custom to place the beds in small cell-like rooms or cubicles which are carefully closed during the night, and he would trace the greater death rate in certain parts of the country as compared with cities as dependent in many cases on the facilities for infection afforded by the confined sleeping-room. The great danger of infection from phthisical patients in lodgings of one room is self-evident He reaches the final conclusion that the decrease in tuberculosis of the lungs is dependent on various factors, the two most important being isolation of patients in hospitals and improvement of the sleeping-rooms and living-rooms

Great difficulties are still in the way before the mortality can be depressed to the lowest possible level The exact statistical determination of the mortality of tuberculosis has been and will be of great value, because the mortality curve at once indicates whether the measures employed are effective Thus, New York City, when its curve began to flatten out, at once resolved to increase its hospital facilities. The same is true of Berlin. To penetrate as deeply as possible into the situation, exact studies should be conducted of smaller districts and towns. Only by so doing will it be possible to secure the greatest help from the lessons obtained from the mortality statistics of tuberculosis. In conclusion we may say then that Koch's last word on tuberculosis is that mortality statistics, carefully obtained and intelligently studied, constitute important factors in our understanding of the subject, which we should utilize to the fullest possible extent as an aid in the prevention of tuberculosis.

THE SEPTIC TANK

The interest that has been expressed in our recent editorial on the septic tank,[1] and the number of inquiries received regarding additional data on the subject, make it seem worth while to give a few supplementary details. The septic tank owes its rather singular name to Donald Cameron of Exeter, England, through whose work about fifteen years ago the so-called septic process of treating sewage first became prominent. The observations on which the process is based are first, the settling out on standing of a considerable proportion of the suspended particles in sewage leading to a sediment or sludge formation, and, second, the dissolving of a part of the sludge, presumably through the activity of bacteria or their enzymes. The partial freeing of sewage from suspended particles by sedimentation was nothing novel, since the advantages of settling tanks, particularly in connection with chemical precipitation, had long been known. On the other hand, the digestion of some of the solid matter of the sewage within the septic tank was supposed to be a feature of very great value. Furthermore, it was believed, although the evidence on this point was never very convincing, that the effluent from septic tanks could be more effectively dealt with than fresh sewage by biologic after-treatment, such as application to contact beds or sprinkling filters. Roughly speaking, then, the septic tank may be looked on as a kind of settling-tank in which the sewage is retained long enough to permit of a diminution in the amount of the sludge and of other chemical changes. The main difference between the settling-tank and the septic tank is the length of time of retention of the sewage.

The diminution of sludge, such as it is, is undoubtedly an advantage. In the early days of septic tank experimentation the amount of sludge digestion seems to have been overestimated. On this point Dunbar of Hamburg, one of the leading students of sewage disposal, writes: "At first it was maintained that the sludge was entirely liquefied and gasified; then that its volume was reduced by 50 per cent., and, as a result of the most recent investigations of which I am aware, it is stated that the amount of sludge is not reduced by more than 9 per cent." For some reason, at present not clearly understood, there seems to be a high degree of variation in the percentage of sludge digestion effected in different septic tanks. Probably differences in the composition of the sewage, in climatic conditions, in size of tank employed and other local factors are in part responsible for the wide range of variation in sludge digestion.

At one time much was hoped from the septic tank in the way of providing a clear and favorable effluent for biologic after-treatment. It was even said with an appearance of precision that the anaerobic changes which took place in the septic tank were essential to prepare the sewage for the aerobic or nitrifying changes which occurred in the filter-bed. On this point faith in the septic tank as a useful adjunct to the purification process has suffered its most grievous disappointment. The effluent from the septic tank is no easier to purify than fresh sewage; indeed, it is more difficult. There is now everywhere agreement among sewage-works engineers that septic action retards rather than facilitates purification both on filter-beds and irrigation fields. The well-known sanitary engineer, Rudolph Hering, has recently expressed the prevailing view where he says that "there is being more and more recognized, on the one hand, the disadvantage of treating foul instead of fresh sewage and the further disadvantage of passing sewage through septic tanks; and on the other hand, the advantage of passing thin layers of fairly fresh sewage over extensive surfaces, exposed to simple attracting forces which segregate the suspended matters."[2]

In answer to the question, therefore, what is gained by allowing a sewage to remain in a settling-tank long enough for decomposition to take place, the reply must be that practically no advantage is obtained. The elaborate experiments which were carried out by Winslow and Phelps[3] on the purification of the sewage of Boston led to the conclusion that the septic tank treatment affords no particular advantage. On the contrary they say: "Since November, 1906, when the distribution system was put in order, crude sewage has been treated on one of our trickling beds with perfect success. The effluent from this filter was less frequently putrescible than that from the bed which received septic effluent. The filter taking septic effluent showed a deposit on its floor, due to secondary reducing changes, which was absent from the crude sewage bed. Furthermore, the absence of the odors produced by spraying septic sewage is an advantage of considerable moment in favor of the process of treating fresh sewage." Recent experiments at Gloversville, N. Y., where the sewage contains a large amount of industrial waste from tanneries, have led to similar conclusions and have shown that while the amount of sludge produced by the septic process is somewhat less than that obtained by sedimentation, this advantage is nullified in other ways as in the tendency towards an increased amount of suspended matter in the septic tank effluent.

---

[1] The Rise and Fall of the Septic Tank, The Journal A. M. A., Nov. 5, 1910, p. 1650

[2] Hering, R.: [illegible] 6, 1910.

[3] Winslow and [illegible] from Sanitary Research Laboratory, Mass. I[illegible]

On the whole, then, it may be said that apart from the advantages that may also be obtained by simple sedimentation (four hours or less), the septic tank has little to recommend it. The slightly increased digestion of sludge is in large degree counterbalanced by the added difficulty of treating the septic effluent. The prevailing opinion among students of the sewage disposal problem is that there is no substantial gain from retaining sewage in tanks until decomposition has set in, but that on the contrary the practice is often distinctly disadvantageous as compared with mechanical sedimentation for a brief period.

THE DEATH OF MRS. EDDY

Announcement has been made of the death of Mrs. Mary Baker Glover Eddy, of pneumonia, at Boston, at the age of 88. Her death marks the close of the first chapter of a most remarkable instance of human credulity—a movement all the more notable in that its origin and development have taken place in the full view of nineteenth century civilization.

Mrs. Eddy has been more fortunate than many other founders of cults and religious teachers. Some of these died before they saw the wide-spread acceptance of their peculiar doctrines, whereas at Mrs. Eddy's death her teachings were followed by thousands in various parts of the world. The beginnings of most movements of this character, and in many cases the personalities of their founders as well, have been shrouded in a veil of mysticism, which has lent an increased attraction and fascination to the susceptible convert and follower. A modern substitute for this mysticism has been afforded to some extent in recent years by the discreet reserve with which Mrs. Eddy's personality has been shielded from public observation. At the same time, the serene unreason of her doctrines has a certain fascination for some otherwise literal-minded individuals, who apparently find in these doctrines and formulas an unforeseen avenue of escape from the harsh tyranny of fact. Perhaps, after all, it is not strange that it should be in the age of material progress—of steam printing-presses, of electric railways and of telegraphs and telephones—that Berkeley's easy short cut out of theoretical materialism should be made the basis of a new cult. "When Berkeley says there is no matter, it is no matter what he says"; but when thousands of people repeat devoutly after Mrs. Eddy, "Mind is all; all is mind" the affair cannot be so lightly dismissed. And on the other hand, not only have modern (and material) methods of communication made possible an unprecedentedly rapid spread of the new cult, but the adherents of that cult have shown a marvelous aptitude for acquiring and making use of those highly esteemed nonentities, cash and credit—and the newspapers. Still, that an unknown, uneducated and almost friendless woman could, from the fifty-sixth to the eighty-ninth years of her life, adapt a creed and establish a cult which would attract many thousands of adherents and draw the attention of the world, cannot but be regarded as a strange and unique chapter in the history of human beliefs and religious vagaries.

It is impossible to determine, at present, what effect her death will have on the movement which she inaugurated. Some years ago it might have precipitated a collapse, but conditions have changed. It must be remembered that for a number of years, Mrs. Eddy has been eliminated from the actual management of the affairs of her following by a well-organized group of experienced business promoters. The principal effect of her death, therefore, for the time being at least, will be a sentimental one. One prophecy, however, may be safely made in the light of the history of other religious movements: the cult will not continue long in its present condition. But whether it will suddenly fall to pieces, as did the following of Dowie after his death, or whether, gradually losing its peculiar features, it will become one of the conventional religious bodies, as have so many similar movements; or whether, broken into warring factions by ambitious and rival leaders, it will gradually disintegrate, time alone will tell. Whatever fate awaits it, however, it is safe to predict, judging from similar movements of the past, that it has reached its high-water mark.

Current Comment

BUSINESS PHILANTHROPY

The linking of the terms "business" and "philanthropy" seems at first sight to be an incongruity or a paradox; and yet business philanthropy is philanthropy in its most effective form. An example of this form of philanthropy is described by Dr. George M. Sternberg[1] in an article on the improvement of housing conditions among the working classes as a factor in the reduction of tuberculosis. In the city of Washington, with its large colored population, with a tendency to overcrowding, tuberculosis has been very prevalent, and this is true also of the white laboring population. As a means of improving the situation and at the same time of securing a reasonable return on the investment, in 1898, Dr. Sternberg, together with some other public-spirited citizens, organized a company for the building of apartments for the laboring classes, which would provide light and air and be equipped with all sanitary conveniences, and which might be rented at a rental compatible with the incomes of that class of people. The houses constructed by this company, and also by other real-estate owners, are of the two-flat type, each flat being entirely independent, having three to five rooms, bath and all sanitary conveniences, and provided with a separate yard. These houses present an attractive appearance; they are built in blocks, often occupying a minor street, formerly an alley, but widened and well paved. Each room is supplied with an abundance of light, and the flats are so constructed as to eliminate all the unpleasant features of the usual tenement houses. The average rental of these houses is $3.25 per month per room, which brings them within the rule that a laborer should pay not more than one-fifth of his income for rental. An admirable device for securing the cooperation of tenants in the care of the apartments is the provision for devoting one month's rent to repairs, and making a rebate to the tenant of this month's rent if no repairs are necessary; otherwise a rebate is made of the difference between the month's rent and the cost of repairs. Nearly 2,000 such houses have been built in Washington. The original company now has $940,000 invested in 289 of these houses, containing 578 apartments; they have paid annually dividends of 5 per cent., besides a surplus of over 20 per cent. of the original capital, which is included in the total investment. It is an evidence of the advantage of hygienic homes for the working classes, and a sufficient justification and reward for this sort of philanthropy, entirely aside from the financial feature, that the death-rate among the tenants of these houses is considerably below the general mortality rates of the city. This is practical philanthropy which is worthy of serious consideration and general imitation.

---

SUPPORT THE HONEST MEDICAL JOURNAL

We have repeatedly called attention to the fact that physicians cannot consistently blame the lay press for carrying lying medical advertisements, so long as they support medical journals which are doing the same thing. Not, of course, that the medical journals advertise nostrums of the "patent medicine" type, but there are many in existence that carry advertisements of so-called ethical proprietaries (save the mark!) whose worthlessness is at least equal to that of the rankest "patent medicine" and the therapeutic claims for which are just as grossly false. The question of nostrum advertising in medical journals is one that can be settled definitely by the medical profession. If physicians will support those journals whose advertising pages are free from pharmaceutical humbugs, the problem is solved. In our previous notices of those independent medical journals, which strive for decency first and dollars afterward, one publication was inadvertently omitted. As the editor states in a letter that appears in this issue,[1] the *Cleveland Medical Journal,* more than a year ago, announced that it would eliminate from its pages, as fast as the contracts expired, all advertisements of medicinal preparations that did not comply with the requirements of the Council on Pharmacy and Chemistry. The last objectionable advertisement appeared in the July issue, and since that time, this journal's pages have been clean from cover to cover. There is no doubt that this stand has been taken at a great financial sacrifice; neither is there any doubt that all right-thinking physicians will approve of the stand; but mere approval will not pay the expenses of publishing a medical journal. The Ohio physicians in general and the physicians of Cleveland in particular should express their approval of clean medical journalism in a concrete and practical way.

THE LOS ANGELES SESSION

As we look forward to the next annual session of the American Medical Association, it is a pleasure to note the activity of the Committee on Arrangements. The chairman, Dr. H. Bert Ellis, Los Angeles, has gathered about him a well-organized committee of the active men of Los Angeles, who are laying plans to show the United States what southern California hospitality means. They call attention to the fact that Los Angeles has several of the finest hotels in the world, as well as many mountain and seaside resorts, flower-laden orange groves, beautiful flower-gardens and parks. One of the complimentary trips will be to some of the orange-groves, where members will be allowed to gather the fruit from the trees. Another trip will be to the famous Catalina Island, twenty-five miles at sea, and will form an auspicious introduction to the Pacific Ocean. The ladies of Los Angeles also are planning to do their part in making the time pleasant for the ladies who accompany the members of the Association. It is not too early to lay plans for the annual outing of 1911, so that it may be taken in connection with the Association's scientific meeting, which is expected to be of the usual high quality. Dr. Ellis will be glad to answer any questions relative to local affairs, while plans for railroad accommodations may be discussed with Dr. M. L. Harris, Chicago, Chairman of the Committee on Transportation.[1]

SIMPLE METHOD OF WATER PURIFICATION

The following simple means of purifying drinking-water is recommended by the provincial health authorities of Ontario to campers, prospectors and travelers. A teaspoonful of chlorid of lime, leveled off by rolling a pencil over it, is rubbed up in a cup of water. This is diluted with three cupfuls of water, and a teaspoonful of this dilution is added to a two-gallon pailful of the water to be purified, mixing it thoroughly. This will give between four and five parts of free chlorin in a million parts of water, which is said to destroy in ten minutes all typhoid and cholera bacilli and dysentery-producing germs, at the same time leaving the water without taste or odor. This has been tried and found effectual, it is said, when used in the germ-laden water of Toronto Bay.

Unobserved Fractures in Early Life.—The child was nursed for three months, and then fed artificially until aged 1 year and 8 months. Then the child "became paralyzed" and screamed whenever he was picked up. *X*-ray photographs showed that there had been a fracture through the upper part of the shaft of the right humerus and another fracture through the lower end of the shaft of the left femur. There was a rachitic condition.—Harold Burrows, *Proc. Roy. Soc. Med.*, July, 1910.

[1] A communication from Dr. Harris on the subject appears in the Department of Association News, page 2078, this issue.

On the whole, then, it may be said that apart from the advantages that may also be obtained by simple sedimentation (four hours or less), the septic tank has little to recommend it. The slightly increased digestion of sludge is in large degree counterbalanced by the added difficulty of treating the septic effluent. The prevailing opinion among students of the sewage disposal problem is that there is no substantial gain from retaining sewage in tanks until decomposition has set in, but that on the contrary the practice is often distinctly disadvantageous as compared with mechanical sedimentation for a brief period.

THE DEATH OF MRS. EDDY

Announcement has been made of the death of Mrs. Mary Baker Glover Eddy, of pneumonia, at Boston, at the age of 88. Her death marks the close of the first chapter of a most remarkable instance of human credulity—a movement all the more notable in that its origin and development have taken place in the full view of nineteenth century civilization.

Mrs. Eddy has been more fortunate than many other founders of cults and religious teachers. Some of these died before they saw the wide spread acceptance of their peculiar doctrines, whereas at Mrs. Eddy's death her teachings were followed by thousands in various parts of the world. The beginnings of most movements of this character, and in many cases the personalities of their founders as well, have been shrouded in a veil of mysticism, which has lent an increased attraction and fascination to the susceptible convert and follower. A modern substitute for this mysticism has been afforded to some extent in recent years by the discreet reserve with which Mrs. Eddy's personality has been shielded from public observation. At the same time, the serene unreason of her doctrines has a certain fascination for some otherwise literal-minded individuals, who apparently find in these doctrines and formulas an unforeseen avenue of escape from the harsh tyranny of fact. Perhaps, after all, it is not strange that it should be in the age of material progress—of steam printing-presses, of electric railways and of telegraphs and telephones—that Berkeley's easy short cut out of theoretical materialism should be made the basis of a new cult. "When Berkeley says there is *no matter, it is no matter* what he says", but when thousands of people repeat devoutly after Mrs. Eddy, "Mind is all, all is mind" the affair cannot be so lightly dismissed. And on the other hand, not only have modern (and material) methods of communication made possible an unprecedentedly rapid spread of the new cult, but the adherents of that cult have shown a marvelous aptitude for acquiring and making use of those highly esteemed nonentities, cash and credit—and the newspapers. Still, that an unknown, uneducated and almost friendless woman could, from the fifty-sixth to the eighty-ninth years of her life, adapt a creed and establish a cult which would attract many thousands of adherents and draw the attention of the world, cannot but be regarded as a strange and unique chapter in the history of human beliefs and religious vagaries.

It is impossible to determine, at present, what effect her death will have on the movement which she inaugurated. Some years ago it might have precipitated a collapse, but conditions have changed. It must be remembered that for a number of years, Mrs. Eddy has been eliminated from the actual management of the affairs of her following by a well-organized group of experienced business promoters. The principal effect of her death, therefore, for the time being at least, will be a sentimental one. One prophecy, however, may be safely made in the light of the history of other religious movements: the cult will not continue long in its present condition. But whether it will suddenly fall to pieces, as did the following of Dowie after his death, or whether, gradually losing its peculiar features, it will become one of the conventional religious bodies, as have so many similar movements, or whether, broken into warring factions by ambitious and rival leaders, it will gradually disintegrate, time alone will tell. Whatever fate awaits it, however, it is safe to predict, judging from similar movements of the past, that it has reached its high-water mark.

Current Comment

BUSINESS PHILANTHROPY

The linking of the terms ‘business" and "philanthropy" seems at first sight to be an incongruity or a paradox; and yet business philanthropy is philanthropy in its most effective form. An example of this form of philanthropy is described by Dr. George M. Sternberg[1] in an article on the improvement of housing conditions among the working classes as a factor in the reduction of tuberculosis. In the city of Washington, with its large colored population, with a tendency to overcrowding, tuberculosis has been very prevalent, and this is true also of the white laboring population. As a means of improving the situation and at the same time of securing a reasonable return on the investment, in 1898, Dr. Sternberg, together with some other public-spirited citizens, organized a company for the building of apartments for the laboring classes, which would provide light and air and be equipped with all sanitary conveniences, and which might be rented at a rental compatible with the incomes of that class of people. The houses constructed by this company, and also by other real estate owners, are of the two-flat type, each flat being entirely independent, having three to five rooms, bath and all sanitary conveniences, and provided with a separate yard. These houses present an attractive appearance, they are built in blocks, often occupying a minor street, formerly an alley, but widened and well paved. Each room is supplied with an abundance of light, and the flats are so constructed as to eliminate all the unpleasant features of the usual tenement houses. The average rental of these houses is $3.25 per month per room, which brings them within the rule that a laborer should pay not more than one-fifth of his income for rental. An admirable device for securing the cooperation of tenants in the care of the apartments is the provision for devoting one month's rent to repairs, and making a rebate to the tenant of this month's rent if no repairs are necessary; otherwise a rebate is made of the difference between the month's rent and the cost of repairs. Nearly 2,000 such houses have been built in Washington. The original company now has $940,000 invested in 289 of these houses, containing 578 apartments; they have paid annually dividends of 5 per cent., besides a surplus of over 20 per cent. of the original capital, which is included in the total investment. It is an evidence of the advantage of hygienic homes for the working classes, and a sufficient justification and reward for this sort of philanthropy, entirely aside from the financial feature, that the death-rate among the tenants of these houses is considerably below the general mortality rates of the city. This is practical philanthropy which is worthy of serious consideration and general imitation.

SUPPORT THE HONEST MEDICAL JOURNAL

We have repeatedly called attention to the fact that physicians cannot consistently blame the lay press for carrying lying medical advertisements, so long as they support medical journals which are doing the same thing. Not, of course, that the medical journals advertise nostrums of the "patent medicine" type, but there are many in existence that carry advertisements of so-called ethical proprietaries (save the mark!) whose worthlessness is at least equal to that of the rankest "patent medicine" and the therapeutic claims for which are just as grossly false. The question of nostrum advertising in medical journals is one that can be settled definitely by the medical profession. If physicians will support those journals whose advertising pages are free from pharmaceutical humbugs, the problem is solved. In our previous notices of those independent medical journals, which strive for decency first and dollars afterward, one publication was inadvertently omitted. As the editor states in a letter that appears in this issue,[1] the *Cleveland Medical Journal,* more than a year ago, announced that it would eliminate from its pages, as fast as the contracts expired, all advertisements of medicinal preparations that did not comply with the requirements of the Council on Pharmacy and Chemistry. The last objectionable advertisement appeared in the July issue, and since that time, this journal's pages have been clean from cover to cover. There is no doubt that this stand has been taken at a great financial sacrifice; neither is there any doubt that all right-thinking physicians will approve of the stand; but mere approval will not pay the expenses of publishing a medical journal. The Ohio physicians in general and the physicians of Cleveland in particular should express their approval of clean medical journalism in a concrete and practical way.

THE LOS ANGELES SESSION

As we look forward to the next annual session of the American Medical Association, it is a pleasure to note the activity of the Committee on Arrangements. The chairman, Dr. H. Bert Ellis, Los Angeles, has gathered about him a well-organized committee of the active men of Los Angeles, who are laying plans to show the United States what southern California hospitality means. They call attention to the fact that Los Angeles has several of the finest hotels in the world, as well as many mountain and seaside resorts, flower-laden orange groves, beautiful flower-gardens and parks. One of the complimentary trips will be to some of the orange-groves, where members will be allowed to gather the fruit from the trees. Another trip will be to the famous Catalina Island, twenty-five miles at sea, and will form an auspicious introduction to the Pacific Ocean. The ladies of Los Angeles also are planning to do their part in making the time pleasant for the ladies who accompany the members of the Association. It is not too early to lay plans for the annual outing of 1911, so that it may be taken in connection with the Association's scientific meeting, which is expected to be of the usual high quality. Dr. Ellis will be glad to answer any questions relative to local affairs, while plans for railroad accommodations may be discussed with Dr. M. L. Harris, Chicago, Chairman of the Committee on Transportation.[1]

SIMPLE METHOD OF WATER PURIFICATION

The following simple means of purifying drinking-water is recommended by the provincial health authorities of Ontario to campers, prospectors and travelers. A teaspoonful of chlorid of lime, leveled off by rolling a pencil over it, is rubbed up in a cup of water. This is diluted with three cupfuls of water, and a teaspoonful of this dilution is added to a two-gallon pailful of the water to be purified, mixing it thoroughly. This will give between four and five parts of free chlorin in a million parts of water, which is said to destroy in ten minutes all typhoid and cholera bacilli and dysentery-producing germs, at the same time leaving the water without taste or odor. Medical News

ARKANSAS

Death of Mrs. Sarah Collings.—The death of Mrs. Sarah Collings, the esteemed wife of Dr. Samuel P. Collings, Hot Springs, is reported. Mrs. Collings has been ill for several months, and her death is a severe shock and a distinct loss to the community, and the cause of deep grief to her many friends in Hot Springs and elsewhere.

Personal.—Dr. Fred Roberts, Lake City, has been elected president; Dr. Rufus W. Ratliff, Jonesboro, vice-president, and Dr. Charles M. Lutterloh, Jonesboro, secretary-treasurer, of the Craighead County Board of Health.——Dr. John P. Brown, Rogers, who has been seriously ill, is reported to be improving.——Dr. S. F. Walker, Texarkana, has been notified by the attorney general that he is entitled to his license to practice, having complied with the provisions of the act of 1903. ——Dr. Charles H. Cargile, Bentonville, was thrown from his buggy in a runaway a mile north of Rodgers, November 5, fracturing his leg.——Dr. John C. Hughes, Walnut Ridge, after a short trial, was exonerated from all blame in the killing of Alf. and I. K. Bagley, father and son, the killing being the termination of a feud.——Dr. Arthur G. Thompson has been elected president of the Pine Bluff Board of Health.

ILLINOIS

Fire in Tent Colony.—Fire at the Bartonville State Hospital, November 29, imperiled the fifty-six tuberculosis patients in that institution, but by energetic work on the part of the fire department of the asylum all were removed without casualty.

Chiropractor Fined.—Walter B. Vogel, a chiropractor of Mount Carroll, charged with *practicing* medicine without a license, is said to have been found guilty, November 23, and fined $200. The defendant gave bonds and says he will appeal the case.

Personal.—Dr. George S. Chalmers, Galesburg, who has been ill, is reported to be improving.——Dr. Fred H. Langhorst, Elgin, has returned from abroad and resumed the practice of his specialty.——Dr. St. Elmo M. Sala, Rock Island, has been elected president of the Rock Island County Society for the Prevention of Tuberculosis.——Dr. Arthur E. Lord, Plano, has returned from abroad.——Dr. Karl F. Snyder, Freeport, has entirely recovered from the accident sustained about two months ago and has resumed practice.——Drs. Joseph De Silva and Albert N. Mueller have been appointed members of the board of directors of the Rock Island Public Tuberculosis Sanatorium.

Chicago

Personal.—Dr. William E. Morgan, who was operated on for appendicitis at Mercy Hospital recently, is reported to be well on the road to recovery.——Dr. Julia Holmes Smith is reported to be seriously ill at her home.

Additional Tuberculosis Nurses.—The directors of the Municipal Tuberculosis Sanatorium have added nine additional nurses to the dispensary department of the institution, bringing the total number of nurses now employed up to twenty-six.

Increase of Diphtheria and Typhoid Fever.—On account of the amount of diphtheria and typhoid fever in Chicago and the steady increase of the number of cases, the department of health has asked and received a special appropriation of $10,000 to be used in fighting the threatened epidemics of these two diseases.

Location for City Sanatorium Fixed.—The city of Chicago is said to have agreed on an eighty-five acre tract of land bounded by Foster, California, Olive, Western, Bryn Mawr Avenues and Rockwell Street, as the location for the new municipal tuberculosis sanatorium. The land is relatively high, being from 18 to 40 feet above the city datum, and is owned by Mrs. Julia F. Porter, who offers it to the city for $100,000.

INDIANA

Pure Drug Organization.—The Indiana Physicians' Pure Drug Association has recently been formed with the object of supporting the state and national pure drug organizations, with the following officers: president, Dr. Edmund D. Clark, president of the Indianapolis Board of Health; vice-presidents, Drs. Frederic C. Heath, Frank M. Morrison, Thomas C. Kennedy and I. H. Roberts, and secretary-treasurer, Dr. Charles E. Cottingham.

Personal.—Dr. Ora L. McCay has returned after a year's absence and resumed practice at Romney.——Dr. Oliver L. Rea, Culver, has moved to Rochester.——Dr. Halsted Murat, Indianapolis, has been appointed assistant physician at the Indiana Reformatory, Jeffersonville, vice Dr. Edward L. Swadener, resigned to enter the government Indian service. ——Dr. Thomas J. O'Neil, Anderson, has been seriously ill with septicemia due to an infected wound of the hand.——Drs. Ralph S. Chappell and M. Cortez Leeth, Indianapolis, have been appointed deputy coroners of Marion County.——Dr. William P. Lane has been elected president, and Dr. I. S. Milstone, secretary of the board of health of Gary.——Dr. Clarence L. Bell, Hartford City, is said to have been declared insane by a medical board recently.——Dr. John W. Snyder, Michigan City, has succeeded the late Dr. J. Lucius Gray, Laporte, as health officer of Laporte County.——Dr. Chester B. Crumpacker, South Bend, has been reelected physician of St. Joseph County.——Dr. Franklin C. Cregor, Greenfield, while making a professional call at the county jail, suffered the loss of a finger by the sudden closing of a heavy door.——Dr. James A. Rawley has leased a two-story house in Brazil, which he is equipping as a hospital.

IOWA

Fire in Tuberculosis Camp.—A fire in the attic of the administration building of the Tuberculosis Camp, Des Moines, November 11, almost destroyed the building with a loss of about $1,000.

Personal.—Dr. Aaron A. Noyes, Mason City, who is still in active practice, celebrated his 88th birthday, November 26. ——Dr. Nic. Gay O. Coad, Hull, and wife have started for the Isle of Pines to spend the winter.——Dr. Walter H. Grimwood, Fort Madison, was operated on November 23, for the removal of gall-stones.——Dr. P. F. Lange has been added to the staff physicians of the Iowa Institution for the Feeble-Minded, Glenwood.——Dr. S. Oliver Stockslager, Boone, is reported to be seriously ill.——Drs. Ray R. Harris and Mathias D. Linehan, Dubuque, have been appointed surgeons of the Burlington System between Dubuque, Lacrosse and Galena.

KANSAS

Tuberculosis Notes.—At a recent meeting of the Kansas Association for the Prevention of Tuberculosis in Topeka, it was decided that the association hire a visiting nurse to travel through the state instructing tuberculosis patients regarding the proper care of themselves and the protection of their families.——At the meeting of the commissioners of Shawnee County, held in Topeka, November 7, it was decided to appropriate $135 a month for the months from October to January, inclusive, for the benefit of the Antituberculosis Camp.

Personal.—Dr. Sarah A. Noble, Clearwater, has located in Chicago.——Dr. M. A. Barber, professor of bacteriology at the University of Kansas, Lawrence, will, it is reported, go to the Philippine Islands at the close of the present school term to spend two years in medical research.——Considerable damage was done by fire to the office of Dr. Simon Steelsmith, Abilene, October 25.——By the will of the late Mrs. Samuel Adams, Powhattan, $25,000 has been devised to Dr. Ralph L. Funk, Powhattan, family physician of the deceased, who was also appointed as executor.

KENTUCKY

Personal.—Dr. Frederick D. Cartwright has been appointed pension examining surgeon at Bowling Green.——Dr. M. L. S. Butner, Shelbyville, was operated on November 23, at Norton Memorial Infirmary, Louisville.——Dr. Bowers, Newport, has been elected a member of the board of health, vice Dr. John Todd, resigned, to accept the position of health officer.

Hospital May Occupy Medical Building.—The Board of Public Safety and Hospital Commission of Louisville are considering the advisability of using the building formerly occupied by the Kentucky School of Medicine as the temporary location of the City Hospital, pending the erection of new buildings. The building in question contains at present about fifty beds.

Jefferson County Institutions.—The grand jury, in its November report, criticizes the condition of the Home for the Aged and Infirm in not having separate quarters for the white and colored inmates; for the uncleanly condition of the bread storeroom, and for an inadequate sewerage system.——The county poor farm was found antiquated, the laundry methods were declared crude and uncomfortable, the cottages housing the inmates old and the heating system was said to be dangerous.——Comment is made on the fact that the excellent hospital department at the Kentucky Institute for the Blind has had no inmate for two years.

Cannot Recover from Medical College.—The Court of Appeals has reversed the decision of the Jefferson County Circuit Court, in which Dr. Harry A. Davidson sued to annul the contract and payment of notes for $3,000 which he gave in consideration of being appointed to the chair of diseases of women in the Hospital College of Medicine before that institution was merged with the Louisville Medical College. The court decided that Dr. Davidson had acquiesced in the merger, and had accepted an appointment in the new institution as professor, and was therefore barred from now making any complaint that the merger terminated the contract. By this decision Dr. Davidson must pay the residue of the notes which he gave for the purchase of the professorship.

MARYLAND

Personal.—The State Board of Health has appointed Dr. Frederick V. Beitler, Halethorp, chief of the Bureau of Vital Statistics, vice Dr. William F. Hines, Baltimore, deceased.——On the occasion of the resignation of Dr. Robert P. Winterode, pathologist at Spring Grove Asylum for the Insane, near Catonsville, he was presented by the nurses and attendants with a handsome meerschaum pipe.

Baltimore

College Suspended.—It is reported that Atlantic Medical College, formerly the Southern Homeopathic Medical College, has been suspended owing to lack of financial support.

Tags for Physicians' Carriages.—The city has issued new tags for the carriages and automobiles of physicians, which instead of the red cross now bear a blue cross on a white field.

New Home for Crippled Children.—Dr. R. Tunstall Taylor, director and chief surgeon of the Hospital for the Relief of Crippled and Deformed Children, Baltimore, announces that James Lawrence Kerman, a wealthy hotel and theatrical man of Baltimore, has purchased for the hospital a new location, known as Radnor Park, in the suburbs of the city. In its new quarters the institution will be known as the James Lawrence Kernan Hospital for the Relief of Crippled and Deformed Children. The property is beautifully located, and the large colonial mansion and other buildings will be utilized for hospital purposes, while other buildings will be erected as necessary. Mr. Kernan has also provided a magnificent permanent endowment for the institution. The present institution will be continued as a reception and emergency hospital.

MASSACHUSETTS

Medical Club Meets.—Brookline Medical Club, at its recent meeting, elected Dr. George W. Kaan, president; Dr. Robert W. Hastings, vice-president, and Dr. H. Hale Powers, secretary-treasurer.

Woman's Medical Society Meeting.—The regular meeting of the Woman's State Medical Society of Massachusetts was held in Boston, November 8. A review of the work of the society of the last year was given. Dr. M. Marie Knudson, sanitary inspector of the Food Department of the Woman's Educational and Industrial Union, presented her report, and Dr. Eliza J. Dadmun, the president, gave an illustrated address on Oberammergau and the Passion Play.

What Is Being Done for Tuberculosis.—The New Bedford Antituberculosis Society moved its twenty-three patients from the old sanatorium building to the new infirmary near Sassaquin, November 29.——The special commission created by the last legislature to investigate and report on a system of caring for tuberculosis patients by state and local authorities recommends that from 5,000 to 6,000 additional beds be provided for such patients, that $5 a week be paid by the state for each non-paying tuberculosis patient in the local hospital, and that a system be established whereby tuberculosis patients may be supplied with food at their homes. The commission finds that there are now about 35,000 cases of tuberculosis in the state, and that for the accommodation of these patients there are at present 2,773 beds in hospitals and sanatoriums.——Fall River has permitted the use of its contagious disease hospital for tuberculosis patients, and fifty have been removed to the institution from the shacks on the Highlands.——Dr. Ralph B. Ober has been elected president of the Springfield Antituberculosis Association, vice Dr. Herbert C. Emerson.

MICHIGAN

The Small-Pox Situation.—The general quarantine against Saginaw was raised December 1, by proclamation of the mayor and on statement of the actual conditions. On October 17 and 18, forty-five cases of small-pox were reported in different parts of the city, and by November 7, 102 cases of small-pox had been reported with twenty-six deaths. Nearly all of the forty-five cases first reported were of the confluent type, and almost all the deaths were among patients of this class. General vaccination has practically stamped out the epidemic, and the expectation is that few more cases or deaths will occur.

MINNESOTA

County Society Meeting.—Mower County Medical Society, at its annual meeting in Austin recently, elected Dr. Charles F. Lewis, president; Dr. G. M. Frank Rogers, vice-president; Dr. Clifford C. Leck, secretary, all of Austin; and Dr. George J. Scottler, Dexter, treasurer.

Plan Sanitarium for Nervous Diseases.—Drs. Arthur Sweeney and Haldor Sneve, St. Paul, and William A. Jones, Minneapolis, have asked authority from the St. Paul City Council to erect a sanitarium in St. Paul, to cost $100,000, for the treatment of nervous diseases.

Unvaccinated Students Excluded from Classes.—By order of President Northrup of the University of Minnesota, about 350 students who had failed to comply with the law that all students should be vaccinated within three days after exposure to small-pox or be excluded from recitations for three weeks, have been excluded from classes.

Home for Crippled Children.—The new Home for Crippled and Deformed Children, adjoining Lake Phalen, St. Paul, is completed, and the installation of the equipment is all that remains to be done before the 100 children, who are now being accommodated in the City Hospital, can be transferred. It is expected that the institution will be fully equipped and ready for occupancy January 1.

Model Isolation Hospital.—Dr. Henry M. Bracken, secretary of the State Board of Health, has been instructed to have plans drawn for an isolation hospital in which to care for persons afflicted with epidemic diseases. This plan is to be kept in the office of the Board of Health and is to be used as a standard for all cities and counties in Minnesota which desire to erect such a building.

Personal.—Dr. Thomas G. Lee, Minneapolis, has returned from Europe.——Dr. Ignatius J. Murphy, Minneapolis, has been appointed inspector of the health department and assistant to Health Commissioner Henry E. Webster.——Dr. Joseph Nicholson, Brainerd, has recovered his health and resumed the management of the Northwestern Hospital.——Dr. Joseph D. Budd, Two Harbors, has been elected president of the Lake County Antituberculosis Society.

MISSOURI

Cocain Peddlers Fined.—Six men, convicted of peddling cocain in Kansas City, were fined sums aggregating $700, November 14. One of the individuals, said to be the executive head of the outlaw cocain business, was fined $200.

New Buildings and Betterments Needed for State Hospital.—New buildings to cost $35,000 are needed at State Hospital No. 2, St. Joseph, and requisitions for betterments and repairs to the old buildings amounting to $50,000 have also been made by the board of managers.

Tag Day in Kansas City.—The Kansas City Hospital Day Association realized $8,430.77 as the proceeds of its third annual tag day, November 19. This money will be divided among the German, Swedish, St. Luke's, St. Mary's, Baptist, Kansas City Post-Graduate and St. Anthony's hospitals, the Florence Crittenden Home and the Visiting Nurses' Association.

Society Meetings.—The seventy-first semiannual meeting of the Rolla District Medical Society was held in Rolla, November 18, and the following officers were elected: president, Dr. Charles F. Briegleb, St. Clair; vice-president, Dr. Samuel B. Rowe, Rolla, and secretary-treasurer, Dr. William H. Breuer, St. James. The next meeting will be held in St. James in May.——The Linton District Medical Society met in Mexico, November 16, and elected the following officers: president, Dr. Frank G. Nifong, Columbia; vice-presidents, Drs. Arthur R. McComas, Sturgeon, and Robert C. Strode, Mexico; secretary, Dr. R. T. Gibbs, Mexico; and treasurer, Dr. Ned R. Rodes, Mexico.——St. Charles County Medical Society, at its annual meeting, November 16, elected the following officers: president, Dr. Samuel R. Johnson; vice-president, Dr. Benedict P. Wentker; secretary, Dr. Thomas L. Hardin; treasurer, Dr. Carl H. Bitter; and censor, Dr. Frank J. Tainter, all of St. Charles.

NEBRASKA

Colored Physician Not Guilty.—Dr. C. A. Flippin, Grand Island, charged with performing a criminal operation which resulted in the death of Julia Kath at Stromsburg, has been acquitted.

Insurance Companies Lose Suit.—The accident insurance companies which had policies on the life of the late Dr. Frederick Rustin, Omaha, have been defeated in their suits to recover the $31,000 insurance involved in the case.

District Society Organized.—Physicians of Chase, Hayes, Dundy and Hitchcock counties met in Wauneta recently, and organized a medical association and elected Dr. Anderw B. Fellers, Palisade, president; Dr. C. E. Stewart, Imperial, vice-president, and Dr. Albert J. Boren, Palisade, secretary-treasurer.

Personal.—Dr. Walter O. Henry has resigned the chair of gynecology in Creighton Medical College, Omaha.——Dr. Louis L. Henninger has located in Omaha as a specialist in diseases of the eye, ear, nose and throat.——Dr. Oscar H. Hahn, Home, Kan., has been appointed medical superintendent of the Nebraska Sanitarium, Hastings.

NEW JERSEY

Hospital Site Abandoned.—Because of the many protests made, the Morris County Antituberculosis Society has abandoned the site in Morris Plains for its sanatorium for tuberculosis.

Personal.—Dr. William D. Miningham, Newark, has started on a trip around the world.——Dr. Frank R. Sheppard, of Millville, made a misstep in the dark, December 1, and fell down a flight of steps, sustaining a fracture of the ankle.——Dr. Herbert Willis, Beach Haven, has been appointed medical examiner of public schools of Tuckerton.

Ice Cream Inspection.—At the meeting of the National Association of Ice Cream Manufacturers held at Atlantic City during the past week, it was announced that out of fifty-one ice cream factories in the state, only fifteen were found that met with the requirements of the law. As a total of 3,000,000 quarts were manufactured in these fifty-one factories during the year, the necessity for laws requiring proper sanitation and greater cleanliness was emphasized.

Children's Seashore House Always Open.—The improvement in chronic cases sent to the Children's Seashore House, Annapolis and Atlantic Avenues, Atlantic City, N. J., chiefly from the hospitals of Philadelphia, in January, 1910, has inspired the management to keep it open the year round. Tuberculous cases are given preference, both in admission and length of stay, but convalescents from acute diseases and other children likely to be benefited by a short stay at the seashore will also be received as there may be room. Cases of pulmonary tuberculosis are not received. Only children between 4 and 12 years of age can be admitted in the winter. Those able to pay are charged $2 a week or less, but no child will be refused admission because of inability to pay. The services of a teacher have been provided for the instruction of such of the chronic invalids as are in a condition to be taught. Those who are able, go to a large sunny school room right on the beach, while those confined to bed are taught in the wards or on the porches.

NEW YORK

Physical Test for Marriage.—A bill drawn by Mrs. Harriet Johnston-Wood and endorsed by the City Federation of Woman's Clubs, is to be introduced into the legislature this session, which provides that all applicants for marriage license shall be obliged to present a clean bill of health.

To Fight Infantile Paralysis.—A request will be made to the new legislature for a special appropriation to permit the State Health Department to make a thorough investigation of the causes and the steps to be taken for the prevention of infantile paralysis. The proposition has the endorsement of the health officers of the state.

Another Typhoid Carrier.—A man who is known as "Typhoid John" is giving the State Health Department and the New York Milk Committee some concern. Last summer there were thirty cases of typhoid in an Adirondack camp. The water and milk supplies were above suspicion. The last person to handle the milk was an Adirondack guide, and he was found to be a typhoid carrier. The man is willing to be treated, which is fortunate, since there is no state law under which he could be detained had he objected.

An Important Court Decision.—Holding that municipalities have no right to pollute public water-courses through their sewage systems the Supreme Court has granted an injunction restraining the village of Sharon Springs from polluting the waters of Brimstone Creek, the waters of which are used by property owners along its course for dairy purposes. The defense of the village was that the state had approved the plans of its sewage system. This was a test case, there being fifty similar suits pending. The court held that it was the policy of the state that water-courses be maintained in a pure and wholesome condition, and that in granting aid to municipal corporations to install sewer systems, the right to maintain a public nuisance was not conferred.

New York City

Flexner Operated On.—Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, who was operated on for appendicitis at the Presbyterian Hospital, December 4, is reported to be doing well.

Fined for Selling Prayers.—Mrs. Eva Stein has paid a fine of $500 in Special Sessions for violating the medical law. She told the agent of the New York Medical Society that the latter had rheumatism and that she would guarantee a cure. She wrote prayers which were to be repeated, and sold them for 15 cents each.

Easy to Buy Red Cross Seals.—The Committee on the Prevention of Tuberculosis of the Charity Organization Society reports through its sales manager that more than 1,800 agencies for the sale of the Red Cross Christmas seals have been opened in Manhattan and the Bronx. They are on sale at every ticket booth of the Hudson tunnel system; all the news stands of the elevated roads also sell the seals. Gifts of advertising space have been made by many of the newspapers and also space in the street cars and in the windows of many stores.

A Good Summer for Babies.—The statistics from St. John's Guild, which operates the Sea Side Hospital, New Dorp, S. I., show that during the past summer the Guild cared for 2,400 mothers and children, 296 less than during the previous season. The number of hospital days of treatment was 20 per cent. less than during the summer of 1909. There were only thirty-eight deaths compared with fifty-one for the summer of 1909. It has been recommended that this hospital, which lies idle during eight months of the year, be used as a convalescent home for infants and their mothers.

The Conference on the Milk Problem.—The conference held under the auspices of the New York Milk Committee at the United Charities Building, passed resolutions advising the investigation of milk production, transportation and distribution, labeling, pasteurization and cooking of milk, and recommending to the city health authorities that special milk for 500,000 infants and children under 5 years of age be immediately obtained. The president of the Board of Aldermen spoke of the city's appropriation of $10,000 to investigate methods of furnishing pure milk. Julius Mildenhawer, assistant in the New York State Agricultural Department, stated that the milk supply was better and safer to-day than ever before. Prof. William T. Sedgewick of the Massachusetts Institute of Technology, was of the opinion that cooked milk, though not so palatable, was by far the safest.

NORTH DAKOTA

Society Meetings.—The Grand Forks Medical Club, at its annual meeting November 4, elected the following officers: president, Peter Nestos; vice-presidents, Herbert Movius and Joseph Martineau, and secretary-treasurer, Fred DuBois.——The Grand Forks Public Health League, at its annual meeting, elected the following officers: president, Dr. Gustave F. Ruediger; honorary vice-presidents, President McVea of the University and Dr. George M. Williamson; and vice-president, Dr. Anders A. Westeen.

Personal.—Dr. John C. Smith, Thompson, has been appointed physician for District No. 3, Grand Forks County, to fill the unexpired term of Dr. Frederick V. Lyman, Thompson.——Dr. William C. Eichler, Underwood, suffered a loss of $500 by fire in his office, November 10.——Dr. and Mrs. Martin W. Roan, Bismarck, have returned from Europe.——Dr. John D. Taylor, Grand Forks, has started for Europe.——The branch station of the North Dakota Public Health Laboratory is to be established at Bismarck under the charge of Dr. Carl T. Raven, formerly city bacteriologist of Oklahoma City.

OHIO

Sanatorium Cottages Opened.—Eight new cottages are now practically completed at the State Sanatorium, Mount Vernon, which will increase the capacity of the institution to more than 200.

Fail to Report Births.—Health Superintendent Ford of Cleveland declares that of 1,400 deaths of infants reported during the last two years not one birth certificate has been filed.

He believes many women are practicing midwifery in the city without license.

Faculty Changes.—Dr. Lyman A. Brewer, associate professor of surgery in Toledo Medical College, has been elected dean of the college, vice Dr. James Donnelly, deceased.——Dr. Perry C. Pike of the University of Pennsylvania has been made professor of physiology in Toledo Medical College.

Alumni Meeting.—The third annual meeting and banquet of the Starling-Ohio Medical Alumni Association of the Miami Valley was held in Dayton, November 22, and the following officers elected: president, Dr. Francis C. Gray, Dayton; vice-president, Dr. Elwood E. Bevington, New Paris; secretary, Dr. G. W. Riche, D.D.S., Dayton; treasurer, Dr. S. Edwards Hendren Dayton, and trustee, H. L. Oliver, D.D.S., Dayton.

Personal.—Dr. Adam L. Jackson, Zanesville, is said to have suffered a cerebral hemorrhage, November 19, and to be in a critical condition.——Dr. Richard A. Bolt, Cleveland, has been appointed medical director of the College of Young China near Pekin. He will teach anatomy, physiology and hygiene.——Dr. William H. Harper, Columbus, received injuries about the legs in a collision between his automobile, a bakery wagon and a street car, November 21.——Dr. George S. Weger, Delphos, is said to have retired from practice to become secretary-treasurer and general manager of the Mueller Implement and Auto Company of that city.——Dr. William F. Teegarden, Columbus, charged with selling liquor in a prohibition district, is said to have pleaded guilty at Marysville, November 12, and to have been fined $75 and costs.

PENNSYLVANIA

Anniversary of Academy.—The Harrisburg Academy of Medicine celebrated its fifteenth anniversary, November 25. Dr. Judson Daland, Philadelphia, delivered an address. Dr. William J. Middleton, Steelton, president, was in the chair, and after the ceremonies, a banquet was served at the Commonwealth Hotel.

Norristown Asylum Report.—The annual report of the Norristown Hospital for the Insane, claims for this year the largest percentage of patients restored since its foundation. Since it was founded, 30 years ago, there have been 13,715 patients treated at the institution. Of these 2,911 have been discharged as restored, 1,991 have improved, 922 are unimproved, 38 were decided not insane and 4,943 died.

Personal.—Dr. Cornelius C. Wholey has been appointed a member of the staff of the St. Francis Hospital, Pittsburg, in charge of the inebriate department.——Dr. Cyril H. Haas, Selinsgrove, is going as medical missionary to Turkey.——Dr. C. Montgomery, resident physician at the Punxsutawney Hospital, was attacked by an insane patient and was saved from severe injury or death only by the timely arrival of assistance.

Medical Club Organized.—The physicians of Armstrong, Butler, Clarion and Venango Counties have formed an organization known as the Foxburg Medical Club, which meets in that city weekly. The object of the organization is the study of medicine in its various phases. At each session, after the scientific papers and discussions are finished, a social hour is spent at lunch at the Foxburg Inn, at which, by common consent, medical subjects are tabooed.

County Societies Elect.—At the annual meeting of the Bucks County Medical Society, in Doylestown, November 9, the following officers were elected: president, Dr. William Martin, Bristol; vice-presidents, Drs. Frank B. Swartzlander, Doylestown, and Harry L. Thomas, Langhorne; secretary-treasurer and reporter, Dr. Anthony F. Myers, Blooming Glen, and censors, Drs. George M. Grim, Ottsville, William R. Cooper, Point Pleasant, and Walter H. Brown, Richlandtown.——A public meeting of the Greene County Medical Society was held in Waynesburg, October 25, when the following officers were elected for the coming year: president, Dr. Thomas L. Blair, Waynesburg; vice-president, Dr. B. L. Cowan; and secretary, Dr. Thomas B. Hill, Waynesburg.

Philadelphia

DaCosta Dead.—As we go to press the notice of the death of Dr. John C. DaCosta, on December 6, is received.

Bottlers Plead Guilty.—Pleading guilty to charges of adulterating their bottled drinks with saccharin, preferred against them by Harry P. Cassidy, special agent of the State Dairy and Food Commission, ten bottlers were fined $25 and costs, November 29.

Measles on Steamship.—The North German Lloyd steamship *Cassel*, from Bremen, which docked November 30, carried more than 1,500 cabin and steerage passengers. A baby died at sea of measles and sixteen other children in the steerage were found to have the same disease and were all sent to the Philadelphia Hospital.

Donation and Bequest.—A donation of $5,000 to the endowment fund of St. Timothy's Hospital has been made by Mrs. Elisabeth L. Clark, in memory of her son, Robert C. Clark. The hospital board will erect a bronze tablet marking the Robert C. Clark bed in perpetuity.——The will of the late Robert O'Donnell bequeaths to St. John's Orphan Asylum and the Little Sisters of the Poor, $1,000 each; to St. Vincent's Home for Infants, St. Vincent's Maternity Hospital, and the Home of the Good Shepherd, $500 each.

Medical Portraits for the University.—Julian Story, the artist, is painting a portrait of Dr. Samuel G. Dixon, State Health Commissioner, which will be hung in the laboratory of pathology at the University of Pennsylvania. The university is also having painted, by Hugh Henry Breckenbridge, a portrait of Dr. James Tyson, recently elected emeritus professor of medicine. A portrait of Dr. Louis Starr, who from 1884 to 1890 was clinical professor of children's diseases, is being painted by Joseph de Camp, and Dr. Simon Flexner, of the Rockefeller Institute, who was professor of pathology from 1899 to 1904, is also sitting for a portrait.

Increased Health Budget.—The Council's Committee on Health and Charities has approved the budget of the department of Health and Charities for 1911, in which Dr. Joseph S. Neff asks an appropriation of $7,127,562 as compared with an appropriation for the current year of $1,016,393. The budget includes an item of $5,000,000 for hospital buildings for the insane on the 800 acres of city land at Byeberry; an item of $100,000 for the Home for the Feeble-Minded; $150,000 for new boilers, dynamos and buildings at the General Hospital; $35,000 for additional fireproof bridges at the Philadelphia General Hospital, and $15,000 for a tuberculosis sanatorium at Byeberry.

Personal.—Dr. Howard S. Anders has been elected fellow of the Royal Meteorological society of London, on account of a series of investigations relating to weather phenomena and influenza epidemics, published since 1898 in the Transactions of the Ame [illegible] Association.——Dr. Claude A. Dundore is [illegible] in Colorado.——Dr. Benjamin A. Thomas has been elected professor of genito-urinary surgery in the Polyclinic Hospital.——Dr. Thomas S. Githens has been appointed to a fellowship in the pharmacologic department of the Rockefeller Institute for Medical Research.——Dr. Louis Mutschler, assistant surgeon in the Episcopal Hospital for ten years, has been elected surgeon.

SOUTH DAKOTA

Personal.—Dr. Charles M. Hollister has been appointed surgeon for the Chicago Northwestern Railroad at Pierre, vice Dr. De Lorme W. Robinson, deceased.——Dr. Frank H. Creamer has been appointed local surgeon of the Milwaukee System at Dupree.

New County Society Meeting.—The Gregory County Medical Society was recently organized at Dallas, and the following officers were elected: president, Dr. Harry A. Murnan, Gregory; vice-president, Dr. Edwin B. Bradley, Burke; and secretary-treasurer, Dr. Thomas R. Castles, Dallas.

State Society Meeting.—The South Dakota State Medical Association held its twenty-ninth annual meeting in Hot Springs, September 27-29. Dr. Hans M. Finnerud, Watertown, was elected president; Dr. Charles E. McCauley, Aberdeen, vice-president; and Dr. Robert D. Alway, Aberdeen, secretary-treasurer. The next meeting will be held in Pierre in June, 1911.

District Society Meets.—The physicians of Pennington, Custer, Fall River and Stanley counties have organized a district society, to be known as the Hot Springs District Medical Society No. 10, and have elected the following officers: president, Dr. Frederick E. Walker, Hot Springs; vice-president, Dr. Frederick W. Minty, Rapid City; and secretary-treasurer, Dr. William E. Robinson, Rapid City.

Black Hills Physicians Hold Meeting.—At the annual meeting of the Black Hills Medical Association, held in Deadwood, November 17, the following officers were elected: president, Dr. Frank S. Howe, Deadwood; vice-president, Dr. Arthur S. Hoon, Nemo; secretary, Dr. Walter L. Vercoe, Lead; treasurer, Dr. Francis E. Clough, Lead; delegates to the state society meeting, Drs. John W. Freeman, Lead, and Frederick A. Brandt, Sturgis; and censors, Drs. John R. Nilsson, Lead: Charles Richards, Sturgis, and Herman F. Ratte, Rapid City.

VIRGINIA

Personal.—Capt. Lyle F. Hansbrough, Front Royal, has resigned from the Medical Corps, Virginia Volunteers.——Dr. Robert C. Randolph, Boyce, is reported to be seriously ill with typhoid fever in Winchester Memorial Hospital.——Dr. Lewis B. Firey, Norfolk, was attacked in his office by two men, November 21, bound hand and foot to a chair, and robbed of $24.

Advocates Hospital for Inebriates.—In the annual report of Dr. John C. King, superintendent of the Southwestern State Hospital for the Insane, Marion, he advocates a separate institution for the care and treatment of individuals addicted to the liquor or drug habit.——Four new buildings have been completed at the State Sanatorium, Catawba, near Salem, which will increase the capacity of the institution to 118.——The new Municipal Tuberculosis Hospital Camp in Henrico County, near Richmond, narrowly escaped destruction by a field fire, November 24.

Medical Society Meetings.—The annual meeting of the Petersburg Medical Faculty was held November 17, and the following officers were elected: president, Dr. W. Preston Hoy; vice-presidents, Drs. Julian R. Beckwith and Robert A. Gamble; corresponding secretary, Dr. Hampden A. Burke, and secretary-treasurer, Dr. William C. Powell.——Rockingham County Medical Society has elected Dr. John F. Wright, Keezletown, president; Dr. Ashby C. Byers, Lacey Spring, vice-president, and Dr. John M. Biedler, Harrisonburg, secretary-treasurer.

GENERAL NEWS

International Dermatologic Congress.—The seventh international congress for dermatology and syphiligraphy will meet at Rome, Sep. 25 to 29, 1911. The questions appointed for discussion are the treatment of syphilis, physiotherapy in treatment of skin diseases, and blastomycosis and sporotrichosis and their relations with analogous affections.

International Prize for Work in Obstetrics and Gynecology.—The surplus left from the international congresses for gynecology and obstetrics in 1892 and 1895 amounts now to about $6,000, and at the fifth congress, recently held in Russia, it was decided to devote most of the income to an international prize for some important achievement or work in the line of obstetrics or gynecology, to be awarded at future congresses. The next congress is to be held in Berlin in 1912. Eclampsia is the chief topic appointed for discussion.

International Hygiene Exposition.—The Germans are making every effort to render the Hygiene Exhibition at Dresden in 1911 an epoch-making educational force, concentrating the results of advanced hygiene and sanitation as achieved in the various countries of the world into a grand object-lesson for comparison and the triumph of the fittest. The exhibition, to which several references have been made in The Journal, includes the five sections, the Scientific, the Historical, the Popular, the Section of Sports and, inseparably connected with them all, Industrial Conditions. The Popular Section is devoted to the whole province of the hygiene of the individual, how to maintain health and strength and improve it under all conditions, and how to rouse the people to a consciousness of the significance and importance of legislative measures enacted in the interests of health protection. The various countries are taking a practical interest in the exhibition, Russia having appropriated 102,000 roubles, over $50,000, and Japan having recently increased its appropriation from $125,000 to $165,000, and speaking for over 1,500 square yards of floor space. The third series of Olympian games is to be held in connection with the exhibition, July 8 and 9, concluding with a climbing trip through the mountainous district nearby. A number of national congresses dealing with matters more or less connected with hygiene are also to be held in connection with the exhibition, the dates of several French congresses of the kind being already announced; among them are the Société Française des Habitations à Bon Marché, several engineering and architect societies, women's clubs, labor unions, etc. Our British exchanges are lamenting that the British government referred to the Board of Trade the invitation to participate in this exposition, and the latter declined, as it had already three industrial expositions on its hands—Brussels, Turin and Rome—so that they say that Great Britain is the only great power which is not to be officially represented. The publicity bureau is issuing once or twice a month for free distribution a circular of "social-hygienic correspondence," which contains many interesting items and data. Address H. Pfeiffer, Zwickauerstrasse 35, Dresden, Germany. Further details of the exposition and its organization were given in The Journal, Oct. 1, 1910.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov. 18, 1910.

Professor Gaucher on Arsenobenzol ("606")

Professor Gaucher, who has succeeded Professor Fournier in the clinic of cutaneous and syphilitic diseases of the Paris medical college, has just devoted one of his clinical lessons to the treatment of syphilis by Ehrlich's method and, in the last session of the Académie de Médecine, he made a report on the same subject. From his personal observation he believes that arsenobenzol does not deserve the name of *therapia sterilisans magna* which Ehrlich has given it. The relapses and the appearance of new manifestations after the injection of this remedy have become innumerable. General paralysis, tabes, the visceral lesions and the quaternary or parasyphilitic lesions, such as lingual leukoplasia, are absolutely intractable to "606." Other forms of syphilis are cured as slowly with "606" as with mercury and potassium iodid. This is particularly the case for the ulcerated gummata. On the other hand, superficial ulcerations and erosive mucous plaques improve very rapidly under "606." Ulcerated and papulous mucous plaques improve much more slowly and sometimes are altogether intractable. Erosive or ulcerated chancres are very quickly cured, but papulous hypertrophic chancres of the skin are cured more slowly. Dry cutaneous lesions are commonly less quickly influenced than ulcerated lesions and often even resist treatment altogether. As for papulous and tubercular lesions, they are cured less rapidly by "606" than under the classical treatment. However, arsenobenzol sometimes gives remarkable results for the tubercular syphilides, as for gummata in cases in which mercury has failed. Gaucher believes that "606" is a remedy which has come to stay but to be used *only exceptionally*. In most cases, mercury treatment ought to be relied on and it ought always to be used first, arsenobenzol being employed only when the patient is intolerant of mercurial preparations or when the latter are ineffective or insufficient. Cases in which mercury is sufficient are very rare, so that there are few indications for the "606." Moreover, it is not a practical remedy. Gaucher has seen patients much weakened by injections; one lost 12 and another 14 kilos (26 and 30 pounds).

Contagiousness of Malta Fever

At the last session of the Académie de Médecine, Professor Widal reported a case of Malta fever which occurred in his own laboratory in an attendant who had taken care of cultures of *Micrococcus melitensis*. In laboratories where the agglutination reaction for Malta fever is often produced, cultures killed by formaldehyd vapor should be used. Moreover, since cases of Malta fever have multiplied in France in the last few years, goats' milk ought not to be used unboiled. The importation of goats from the island of Malta ought to be prohibited in French ports as it has already been in the ports of Tunis. On the motion of Dr. Widal, the academy passed a resolution that Malta fever ought to be included in the list of diseases compulsorily reportable.

Professor Grasset on the Medical Crisis

At the opening session of the University of Montpellier, Professor J. Grasset made an address in which he answered objections to the *concours d' agrégation*. He believes that the training of the clinician in Germany and in England is much inferior to that in France. In Grasset's opinion, the German privat-docent system is the *most* undemocratic imaginable. He declares that it is not the preservation or suppression of the *concours* that ought to cause disquietude; it is something more serious: the "phobia of inequality" with which the medical profession is imbued.

Plans for the Formation of a Medicolegal Institute

In one of my previous letters (The Journal, Jan. 15, 1910, p. 215) I noticed the plan for the reorganization of the morgue. The Minister of Public Instruction has just presented a bill for the foundation in Paris of a medicolegal institute, comprising all the administrative and educational services installed in the morgue building, which will make investigations to identify unknown bodies, perform judicial necropsies and give expert medicolegal opinions as well as instruction with laboratory and practical work in legal medicine. For instruction and scientific research, the institute will be connected with the Paris Medical college, which will have free disposition of unclaimed bodies left in the institute.

Abuse of the Red Cross Emblem

In *Caducée*, a journal of military medicine, Dr. Granjux has undertaken a campaign for the prohibition of the abuse of the

Red Cross emblem in France At the time of the revision of the Geneva Convention, in 1906 an article was voted requiring all the states which signed the convention to prevent the use of the emblem and even the name of the Red Cross or Geneva Cross by private individuals or by societies not entitled to it, and especially for commercial purposes as a trade mark A maximum period of five years was allowed the governments to put these measures into effect Some countries have already forbidden the abuse of the emblem, but in France one may still see used red crosses on the signs of pharmacists, on nurses' houses and on ambulances

Homage to Professor Bernheim

On the retirement of Dr H Bernheim, professor of clinical medicine at the Nancy medical college, his collaborators and friends presented him with an artistic medal Several addresses were given, especially by Dr Gross, dean of the Nancy medical college and by M C Adam, rector of the university Dr Bernheim gave an interesting review of his whole life, first in Strasburg before the war of 1870 71, then in the army ambulance service during that campaign and finally, since 1872 at Nancy, where he has been occupied since 1883 with the subject of suggestion, taking sides against the school of the Salpêtrière represented by Charcot

Measures Against Alcoholism

Taking the stand that the greater number of crimes committed are the direct result of alcoholism and that the latter constitutes a veritable social scourge which must be checked most energetically, the jury of the Seine in November passed the following resolution (1) that every individual found drunk on the public thoroughfare ought to be immediately arrested and brought before the courts, (2) that for ten years, all granting of licenses ought to be absolutely prohibited.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, Nov 10, 1910

Suicide Statistics

According to the statements made by Dr Schilling, the frequency of suicide in Europe has increased since 1831 by 400 per cent, while the growth of the population is only 60 per cent From 1869 to 1872 there were 72 suicides to 1,000,000 inhabitants in Prussia, while from 1891 to 1900 there were 60,518 In the German empire the number of suicides for 1881 was 9,944, for 1903, 12,730 Even the suicide of children has continually increased Only in a few countries, such as Norway, Denmark and Spain, has the number of suicides decreased In addition there is no doubt that, as a rule, the number of suicides is materially larger than the official figures, as cases of suicide are frequently concealed Among the methods, hanging is most frequently employed Of 100 suicides during the years 1883 to 1890, 57 3 to 62 hung themselves, 17 to 20 drowned themselves, 9 4 to 12 8 shot themselves, and in the fourth place come those who stab themselves and fifth, those who take poison More unmarried persons kill themselves than married, more single women than single men, more widowers than widows Among motives, love and jealousy predominate among the women, alcoholism furnishes many victims As to age a suicide under five is scarcely known and the rate constantly increases from five to twenty five and then falls off somewhat until the fiftieth year, and again increases during old age Suicide is scarcely influenced by climatic conditions, but the season of the year has an especial importance In summer the cases are most frequent and least so in December Also with reference to the time of day there are differences The largest number of suicides occurred between 6 and 12 a m and 2 to 6 p m With reference to profession and occupation, there were in Prussia from 1883 to 1890 for 100,000 inhabitants only 40 suicides among those in business for themselves, 61 among public officials, 63 among private officers, 40 among laborers and servants, 59 among persons in the army, 84 among those having incomes and pensions and 67 among the recipients of charity

Alcoholism and Mental Diseases

From his investigations in the insane asylum at Frankfort a M on the question to what extent alcohol is to be regarded as the cause of insanity, among a total of 2 032 who were received in 1907 08 with a history of alcoholic antecedents, Dr Sichel found drunkenness of the parents or near relatives in 308 cases The alcoholic taint was distributed as follows among the various forms of mental disease Chronic alcoholism 39 9 per cent, imbecility and idiocy, 16 4 per cent, dementia præcox, 14 3 per cent, depressive mania, 3 6 per cent, epilepsy, 15 2 per cent, hysteria, 7 5 per cent, traumatic psychoses, 0 6 per cent, paralysis and organic psychoses, 4 6 per cent, senile psychoses, 1 6 per cent, psychoses of other forms, 2 3 per cent, psychoses and alcoholism, 17 2 per cent The fact first recognized by Sioli that there is a homogeneous inheritance of particular forms of mental disease is also evident here, two fifths of the patients tainted by the drunkenness of their parents become drunkards, and alcohol plays a large rôle in the psychoses of another fifth The majority of the patients were received on account of alcoholic disturbances, especially delirium tremens Next in frequency come epilepsy and dementia præcox With reference to the other psychoses it should not be overlooked that in addition to alcoholism in many cases there were other forms of inherited taint

Those with alcoholic inheritance show in comparison with other insane a predominance in the first decade, the children of drunkards need institutional treatment earlier than others Among the 308 patients there were thirteen children of and under school age The maximum of admissions among those with alcoholic taint, as well as with other mental diseases, falls in the fourth decade The data with reference to the offspring of patients coming from families of drunkards are below the reality, as they represent a minimum obtained from the historical data The percentage of sterile marriages is strikingly large Among 130 married patients 22 marriages were without offspring (not even stillbirths or miscarriages), of 10 marriages nothing could be learned From the remaining 98 marriages there were 205 children who might be designated as healthy, and 118 of whom no exact information could be obtained, 52 were not carried to full term, 20 were stillborn, 75 died soon after birth 21 of convulsions, 32 of infectious diseases Altogether 200 individuals perished at birth or soon after Among the survivors diseases of the nervous system appeared at an early date in a considerable percentage Here the figure obtained is surely below the truth Some were already in institutions, others had left home and were lost sight of The patients of the institution are drawn from all classes of the population but the group under consideration belongs in the great majority to the lower classes Among the victims of alcoholism the effort to raise their offspring above their own social level appears to be totally lacking, 61 per cent of the patients were paupers

On the relations of alcoholism to etiology of epilepsy, Dr M Muller has investigated the material of the Swiss institutions for epileptics The material of the Zurich institute for the years from 1896 to 1907 showed that among 503 patients admitted, a history of alcoholic taint was obtained in 369 cases These showed alcoholism in the progenitors in 33 99 per cent, psychoses and neuroses in 29 22 per cent, epilepsy in 10 13 per cent He remarks that collective statistics cannot lead us much further in the investigation of the conditions of heredity but that there is need of study of the individual family in order to gain a deeper insight into the matter He has the tabulated details for thirty families all of which show analogous conditions The number of inferior members is very large The appearance of affections of the nervous system and of other organs such as tuberculosis and carcinoma is frequent The parents of the patient show no abnormalities, but the grandparents and the collateral lines on the mother's side are characterized by abnormalities of all sorts The inferior germ plasma came into the family through the mother and this inferiority was occasioned by the alcoholism of the grandparents, in the mother it remained latent Epilepsy in these families is of a severe type and associated with physical inferiority Very often the only heredity in the direct line of the mother is alcoholic and the healthy germ plasma of the father is unable to neutralize this injurious influence The simultaneous occurrence of alcoholism or alcoholic taint on the paternal side is correspondingly graver As to the relations of individual alcoholism to epilepsy, Muller is of the opinion that an epilepsy generated by the use of alcoholic drinks in a healthy constitution does not exist but that the use of alcohol in a nursing woman may produce epileptic convulsions in the infant

Bill for a Law Against Quackery

The antiquackery bill which I mentioned some time ago has just passed the senate Whether it will meet the wishes of the medical profession and is suited to restrain the growth of quackery remains to be seen Also it is a question what position the Reichstag, the lower house whose consent is necessary for the enactment of the law, will take in reference to this bill

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Nov. 22, 1910.

A General Medical Tariff for Prague

The physicians of Prague have, after repeated efforts, succeeded in convincing all members of the local medical association of the necessity for a minimal tariff for professional services. In a memorandum addressed to the general public, the necessity of having a fixed tariff is explained by the frequent disputes between patients and doctors as to fees and by the increase of the general cost of living. The tariff divides the doctors into general practitioners, specialists and consultants. The last-named doctors are not bound to any fixed sum, but they may not go below the usual terms of specialists. The general practitioner must charge at least 2 kronen (40 cents) for a consultation in his office and 3 kronen (60 cents) for a visit in the patient's house. Night visits to be charged for at double rates of the day fee. Specialists have to charge double the rates of the ordinary doctor's fee. This is only the lower margin, as of course no upper limit can be fixed. All consultations by telephone, all written testimonials, all surgical dressings and appliances shall be charged for, the latter according to their actual cost, the former at the rate of 2 kronen each. The fee shall be due when the treatment or attendance on the patient ends. Accounts shall be sent in every quarter of the year; for fees due longer than a year, the doctor shall be entitled to ask interest at the rate of 5 per cent.

Mortality and Health of the Jewish Population in Vienna

A remarkable report by the Jewish board of health of Vienna has just now been published. It is interesting to compare its figures with those of the Gentile population. In 1909, there were 180,000 Jews among 2,100,000 of Viennese inhabitants, or a little less than 9 per cent. They have increased by 4 per cent. against 2 per cent. of the other part of the population, when the year 1908 is considered. There were 2,502 children born alive. The increase by births was 7.5 per cent. The percentage of childbirth at Vienna generally, is less than 1 per cent. The Jewish mortality was 125 per 1,000. The general Vienna mortality was 16 per cent. in 1909. A large number of deaths was due to senility: more than 20 per cent. of the deaths happened at ages over 75. It is interesting to note that only 185 Jewish infants under one year of age died in 1909, less than 9 per cent. of all deaths. Among the Jews, there is a marked freedom from alcoholism and its sequelæ; diabetes, obesity, leukemia and neurasthenia are very frequent complaints, according to hospital registers, while insanity is not more frequent than in the whole community. Taken all in all, the Jewish population in Vienna is an excellent example of the value of long-continued observations of hygienic principles; for as such, most of their religious rules regulating their living must be regarded. The special care paid by them to children, the absence of factory working by mothers, tends to propagate a healthy stock of people up to a high age.

Marriages

Bohumur J. Dvorsky, M.D., to Miss Rose M. Votipka, both of Chicago, November 24.

Frank Brouwer, M.D., to Mrs. Alida Kirk, both of Toms River, N. J., November 25.

Harrison S. Thurston, M.D., to Miss Ella C. Shannon, both of Indianapolis, November 23.

Walter O. Gray, M.D., Worland, Wyo., to Miss Mary Forbes of York, Neb., November 24.

James G. Marron, M.D., Brainard, Neb., to Mrs. Frances Barnforth of Omaha, November 17.

Joel D. Whitaker, M.D., Raleigh, N. C., to Miss Melissa Myers of Logansport, Ind., November 22.

David J. Hale, M.D., Las Cascadas, C. Z., to Miss Edith Dean of Mount Pleasant, Mich., recently.

Joseph C. R. Doggett, M.D., Crane, Mo., to Miss Erma Ethel Craig of Galena, Mo., November 20.

Joseph Lane Finley, M.D., Betterton, Md., to Mrs. Emma R. Baughman, at Baltimore, November 23.

Charles Henry McDonald, M.D., to Miss Vesta L. Vradenburg, both of Arthur, Ill., November 17.

Claude Smith Black, M.D., Warren, Ind., to Miss Hallye Nelson of Greencastle, Ind., November 16.

Albert L. Sibold, M.D., McDonald's Mill, Va., to Miss Addie V. Parks, at Baltimore, November 19.

Herman Theodore Bechtold, M.D., O'Falion, Ill., to Mrs. Elle Merch-Bechtold of Belleville, Ill., November 17.

Joseph W. Shaw, M.D., Buckville, Ark., to Mrs. Susie Johnson of Lena, Ark., at Hot Springs, November 21.

Guy Dawson Rutledge, M.D., Junction, Utah, to Miss Anna Mary Fletcher of Smithshire, Ill., October 20.

Russell Wesley Raynor, M.D., White Haven, Md., to Miss Lola E. Wilson, at Deal's Island, Md., November 20.

Leslie Erwin Coffin, M.D., Iron Mountain, Mich., to Miss Emily May Beeson of Marshalltown, Ia., October 27.

Howard Stanley Gorsuch, M.D., to Miss Clara Strauff, both of Baltimore, at Wilmington, Del., November 22.

Charles Waite Orville Bunker, M.D., U. S. Navy, to Miss Eleanor Garrett Caldwell, at New York City, November 12.

Deaths

Landon Brame Edwards, M.D. New York University, New York City, 1867; for many years secretary of the Medical Society of Virginia; one of the founders of the University College of Medicine; founder in 1874 and for many years editor of the *Virginia Medical Monthly*, later known as the *Virginia Medical Semi-Monthly;* died at his home in Richmond, November 27, aged 65. In 1863, Dr. Edwards enlisted in the Artillery Corps of the Confederate army and served until the close of the war, and served afterward as surgeon of the First Regiment, Virginia Volunteers. He attended his first course of medical lectures at the University of Virginia. In 1868 he moved to Lynchburg, where he remained until 1872, when he removed to Richmond. He was a member of the American Medical Association; a charter member of the Medical Society of Virginia and recording secretary since 1870; a member of the Southern Surgical and Gynecological Association; past president and honorary fellow of the Richmond Academy of Surgery; from 1872 to 1908 he was a member of the State Board of Health. His work as a teacher began in 1874, when he became lecturer on anatomy in the Medical College of Virginia; in 1875 he was elected lecturer on materia medica and therapeutics and served in this capacity for two years. In 1893 he was made professor of practice of medicine in the University College of Medicine, Richmond, and from 1900 to 1907, was professor of clinical medicine and dean of the medical faculty of the institution and later emeritus professor. His hospital experience began in 1867, when he served for five months as house physician at Charity Hospital, Blackwell's Island, and later as assistant physician to Dr. M. Gonzales Echeverria, at his hospital for nervous diseases, Lake Mahopac, N. Y. In 1902 Dr. Edwards was elected an honorary member of the Medical Society of Virginia, and at the session of that body in Roanoke, in 1909, he was presented with a purse containing $1,000 as a token of the affection in which he was held by the members.

David Nathaniel Kinsman, M.D. A veteran physician and educator and public-spirited and progressive citizen of Columbus, O.; died at his home in Columbus, November 24, from heart disease, aged 76. Dr. Kinsman was graduated from the Medical College of Ohio, Cincinnati, in 1863, and since 1866 practiced in Columbus. He was a member of the American Medical Association; formerly president of the Ohio State Medical Society; a member of the American Academy of Medicine, and Columbus Academy of Medicine: a member and first president of the Columbus Medical Society in 1882. From 1872 to 1874 he was professor of diseases of women and children in Starling Medical College: professor of practice of medicine in Columbus Medical College from 1875 to 1892; professor of nervous diseases in Starling Medical College from 1892 to 1898; professor of practice of medicine in Ohio Medical University from 1898 to 1907, and thereafter emeritus professor. For many years he was chief of staff of the Protestant Hospital, Columbus. He served as health officer of Columbus from 1893 to 1897, and was a member of the Ohio Live Stock Commission from 1886 to 1900. At a meeting of the physicians of the city, November 27, presided over by Jesse A. Van Fossen, Dr. John H. J. Upham spoke in laudation of "Dr. Kinsman, the Teacher;" Dr. John M. Dunham on "Dr. Kinsman, the Advisor;" Dr. Theodore W. Rankin on "Dr. Kinsman, the Physician and Student," and Dr. John W. Wright, on "Dr. Kinsman as a Friend and Associate." Dr. Florus F. Lawrence then narrated numerous instances of sacrifices made by Dr. Kinsman for the sake of friends and patients.

Christian Archibald Herter, M.D., treasurer of the Rockefeller Institute for Medical Research, and one of the board of five referees appointed by the President of the United States to act as advisers of the Department of Agriculture in the enforcement of the national Food and Drugs Act, died at his home in New York City, December 5, aged 45. He was a native of Glenville, Conn., received his preliminary academic education in New York City, and was graduated from the College of Physicians and Surgeons in 1885. His especial work was that of an investigator and chemical pathologist. He was professor of pathologic chemistry in the University and Bellevue Hospital Medical College from 1898 to 1903, and professor of pharmacology and therapeutics in the College of Physicians and Surgeons since that time. Dr. Herter was a prolific writer, his more ambitious works being those on "Diagnosis of Nervous Diseases," published in 1890, and "Lectures on Chemical Pathology," which appeared twelve years later. From 1894 to 1904, Dr. Herter was visiting physician to New York City Hospital. He was a member of the American Medical Association, New York Academy of Medicine, Association of American Physicians, American Physiological Society, American Society of Experimental Biology and Medicine and other scientific bodies. Dr. Herter had been in ill health for more than a year, but his death was due to pneumonia.

David Lynn Magruder, M.D. University of Maryland, Baltimore 1849, Brigadier General, Medical Corps, U. S. Army, retired, died at his home in Bryn Mawr, Pa., November 22, aged 85. He entered the Army as an assistant surgeon in 1850; was made captain five years later, in 1862 he was made major, in 1882, lieutenant colonel, in 1886, colonel, and was retired April 23, 1889, by operation of law on account of age. He served as medical director of the Department of the Missouri at St. Louis until October, 1863, and then became chief medical purveyor at Louisville. After service as medical director of the departments of the Platte and Arizona, he again served as medical director of the Department of the Missouri, until 1884. He was brevetted lieutenant colonel in 1865 for faithful and meritorious service during the war, and was advanced to brigadier general on the retired list in 1904 on account of Civil War service.

Frederick W. Van Slyke, M.D. Minnesota Hospital Medical College, Minneapolis, 1883, a member of the American Medical Association, Minnesota Valley Medical Society, American Academy of Ophthalmology and Oto-Laryngology, and the Heidelberg (Germany) Ophthalmological Society, ophthalmologist and otologist on the staff of the City and County Hospital, St. Paul, University Free Dispensary and Protestant Orphan Asylum, died in St. Joseph's Hospital, St. Paul, November 23, from hemorrhage of the stomach, aged 53.

John D. Axline, M.D. Medical College of Ohio, Cincinnati, 1869, a member of the American Medical Association, a veteran of the Civil War, and first president of the Red, White and Blue Society, of which the Grand Army of the Republic was an outgrowth, for twenty-six years local surgeon of the Baltimore and Ohio Railroad at Shawnee, O., for twelve years surgeon of the C. H. and S. Railroad, a member of the Seventieth General Assembly of Ohio, died at his home in Shawnee, November 19, from diabetes, aged 68.

Samuel Alexander, M.D. Bellevue Hospital Medical College, 1882, a member of the American Medical Association, New York Academy of Medicine, New York Surgical Society, and American Association of Genitourinary Surgeons, professor of diseases of the genitourinary system in Cornell University, surgeon to Bellevue Hospital, and consulting surgeon to the Montefiore Hospital, died in the New York Hospital, November 29, after an operation for appendicitis, aged 52.

James H. Green, M.D. Medical College of Ohio, Cincinnati, 1884, a member of the American Medical Association, Association of Surgeons of the Baltimore and Ohio Railway, Big Four Railway Surgeons' Association, and National Association of United States Pension Examining Surgeons, local surgeon at Mount Vernon, Ind., for the Big Four and Baltimore and Ohio systems and local member of the pension board, died at his home, November 21, from nephritis, aged 51.

Oliver Roland, M.D. University of Pennsylvania, Philadelphia, 1875, a member of the American Medical Association, for many years a member of the school board and board of health of Lancaster, Pa., for twenty years physician to the Children's Home and Hospital, attending physician to St. Joseph's Hospital, and consulting physician to the Lancaster General Hospital, died at his home, November 20, from cerebral hemorrhage, aged 60.

William Robert Bross, M.D. College of Physicians and Surgeons, New York City, 1881, formerly a railway surgeon in Costa Rica, and port health officer of Port Limon, a member of the yellow fever commission for South America, since 1889 a member of the staff of the Equitable Life Assurance Company, and for several years medical director of the company; died at his home in Babylon, L. I., November 21, from cerebral hemorrhage, aged 56.

Alvah Coit Van Syckle, M.D. New York University, New York City, 1878, a member of the Medical Society of New Jersey, and vice-president of the Tri-County Medical Society, twice mayor of Hackettstown, a member of the board of education, and president of the Warren County Medical Society, died suddenly while attending a meeting of the society, November 22, from heart disease, aged 57.

Robert Quincy Gray, M.D. Washington University, St. Louis, 1907, a member of the Missouri State Medical Association, formerly a practitioner of Cabanne, Mo., later surgeon to the Guggenheim lead mines in Mexico, died in a hotel in San Antonio, Texas, November 24, from the effects of a gunshot wound believed to have been self-inflicted with suicidal intent, aged 27.

David Sisson, M.D. Physio-Medical Institute, Cincinnati, 1876, a member of the American Medical Association, a veteran of the Civil War, for several years secretary of the Ohio Valley Medical Association, for several years health officer of Middleport, Ohio, at one time assessor of Yuma County, Colo., died at his home, November 15, from cardiac asthma, aged 66.

William Watson, M.D. Rush Medical College, 1854, surgeon of the Eleventh Iowa Volunteer Infantry during the Civil War, and for two years surgeon-in-chief of the Military Hospital, Rock Island, Ill., a practitioner of Dubuque, Iowa, until 1901, and thereafter of River Forest, Ill., died at the home of his son in that place, November 21, from the effects of a fall, aged 84.

Stephen G. Cook, M.D. New York University, New York City, 1857, for twenty-five years police surgeon of New York City, and formerly president of the Board of Police Surgeons; surgeon of the One Hundred and Fiftieth New York Volunteer Infantry during the Civil War, died at his home in New York City, November 21, from senile debility, aged 79.

William H. Williams, M.D. Western Reserve University, Cleveland, 1900, for six years local surgeon of the Lake Shore System and superintendent of the board of health at Collinwood, Ohio, and mayor of that city in 1909 and until it was annexed to Cleveland, died in the Charity Hospital, Cleveland, November 17, from heart disease, aged 40.

J. G. Cox, for sixty years a practitioner of medicine of Jacksonville, Ill., and Humboldt, Neb., a veteran of the Mexican War, assistant surgeon of the One Hundred and Fiftieth Illinois Volunteer Infantry during the Civil War, died at his home in Humboldt, Neb., July 15, from senile debility, aged 87.

Frank E. McGann, M.D. Barnes Medical College, St. Louis, 1904, a member of the Illinois State Medical Society and coroner of Brown County, and formerly secretary and treasurer of the Brown County Medical Society, died at his home in Mount Sterling, November 28, from pneumonia, aged 30.

Thomas Lincoln Wells, M.D. Bellevue Hospital Medical College, 1883, a member of the Medical Society of the State of New York, and Brooklyn Neurological Society, formerly a member of the staff of the State Hospital for the Criminal Insane, died at his home in Brooklyn, October 20, aged 49.

Jesse M. Jones (license, Ind., 1897), a member of the Indiana State Medical Association, a practitioner of Indiana for forty-two years, for four years member of the Pension Examining Board of Cataract, Ind., a veteran of the Civil War, died at his home, November 1, aged 75.

Charles L. Mitchell, M.D. Jefferson Medical College, 1880, one of the founders of the Medico-Chirurgical College of Philadelphia and for many years professor of chemistry in that institution, died in Presbyterian Hospital, Philadelphia, November 24, from heart disease, aged 58.

Linn Archibald Kelly, M.D. Bennett Medical College, Chicago, 1869, a member of the school board and city physician of Winona, Minn., a member of the local board of U. S. pension examiners, died at his home, November 24, from septicemia due to an operation wound, aged 65.

George Henry Plitt, M.D. State University of Iowa, Iowa City, 1895, a member of the Kentucky State Medical Association, representative from Hancock County in the state legislature, was found dead in his home at Lewisport, November 22, from heart disease, aged 39.

Robert C. Tuttle, M.D. Albany (N. Y.) Medical College, 1863; assistant surgeon in the U. S. Navy from 1862 to 1866; formerly of Rockland, N. Y., but for ten years past associated with his son at Roscoe, N. Y.; died at his home, November 10, from angina pectoris, aged 76.

Albert Berry Clanton, M.D. Jefferson Medical College, 1852; of Hattiesburg, Miss.; a lieutenant in the Mexican War, and a surgeon in the Confederate service during the Civil War; died at the home of his daughter in St. Louis, February 17, from pneumonia, aged 81.

George R. Millhouse, M.D. Columbus (Ohio) Medical College, 1878, a veteran of the Civil War, formerly of Allentown and Elida, Ohio, but for some time past a resident of Lima; died at the home of a niece in Piqua, Ohio, October 22, from heart disease, aged 70.

John Henry Shenk, M.D. University of Pennsylvania, 1861; a member of the Medical Society of the State of Pennsylvania; formerly school director and a member of the Lititz city council, died at his home, November 23, from uremia, aged 71.

John W. Cringan, M.D. University College of Medicine, Richmond, Va., 1901, of Arrington, Va.; a member of the American Medical Association, died on a Chesapeake and Ohio train at Ashcake, Va., November 22, from heart disease, aged 33.

John Thaddeus Carter, M.D. Cleveland University of Medicine and Surgery, 1890, professor of chemistry, toxicology, analysis, and physiology in Cleveland Medical College, died at his home in Cleveland, November 19, from nephritis, aged 48.

Harry S. Ford, M.D. McGill University, Montreal, 1904, of Vancouver, B. C., died about November 10, from exposure, while lost in a forest near Jervis Inlet, 130 miles north of Vancouver, where he had been on a hunting trip, aged 30.

George Anthony Byrs, M.D. Rush Medical College, 1855, assistant surgeon of the One Hundred and Nineteenth Illinois Volunteer Infantry during the Civil War, died at his home in Clayton, Ill., October 25, from senile debility, aged 81.

Daniel O'Callaghan, M.D. Trinity College, Dublin, Ireland, 1871; Jefferson Medical College, 1882; for ten years a practitioner of London, and later of Kensington, Philadelphia; died at his home, November 13, from pneumonia, aged 71.

Herbert Charles Switzer, M.D. Detroit College of Medicine, 1902, a member of the American Medical Association, formerly of Gaines, Mich.; died at his home in Highland Park, Detroit, November 28, from pneumonia, aged 36.

James Hugh Bledsoe, M.D. Jefferson Medical College, 1891; formerly vice president of the Marshall County (Tenn.) Medical Society, died at his home in Yokely, near Lynnville, Tenn., November 17, from pneumonia, aged 41.

James Pollock McCleery, M.D. Jefferson Medical College, 1857, surgeon of the Fifty-Sixth Pennsylvania Volunteer Infantry during the Civil War; died at his home in Milton, Pa., November 25, from paralysis, aged 78.

Robert Wallace Jakes, M.D. McGill University, Montreal, 1893, died at his home in San Francisco, November 20, from the effects of cyanid of potassium, believed to have been self-administered with suicidal intent, aged 40.

Sidney C. Burgess, M.D. University of Arkansas, Little Rock, 1886, president of the Polk County (Ark.) Board of Health; local surgeon at Russellville for the Missouri Pacific System; died at his home, November 12, aged 51.

William C. P. Butman, M.D. Albany (N. Y.) Medical College, 1854, assistant surgeon of the Third Missouri Volunteer Infantry throughout the Civil War; died at his home in Macon, Mo., November 12, aged 83.

Howard C. Brown, University College of Medicine, Richmond, Va., 1899, of Blythedale, Md.; while waiting for a train at Newark, Del., November 24, was struck by a train and instantly killed, aged 35.

William L. Miller, M.D. George Washington University, Washington, D. C., 1883; a member of the Medical Association of the District of Columbia; died at his home in Washington, November 20, aged 51.

Edmund D. Burwell, M.D. Louisville Medical College, 1875; a member of the Medical Association of the State of Alabama; died at his home in Huntsville, November 6, from intestinal miliary tuberculosis, aged 62.

Elam Bahr Mauger, M.D. Jefferson Medical College, 1875; a member of the Medical Society of the State of Pennsylvania, died at his home in Pottstown, November 20, from angina pectoris, aged 57.

John H. O'Bar, M.D. St. Louis College of Physicians and Surgeons, 1908; professor of fractures and dislocations in his alma mater; died in the O'Bar Sanitarium, St. Louis, November 22, from pneumonia, aged 39.

Leonard M. Mingos, M.D. Chicago Homeopathic Medical College, 1878; of Towanda, Pa.; died at his country home in Danville, N. J., November 3, from injuries received in a runaway accident, aged 56.

Homer L. Rochelle, M.D. Western Eclectic College of Medicine and Surgery, Kansas City, Kan., 1908; of Kansas City; died in Hot Springs, Ark., November 23, from nephritis, aged 48.

Martin Luther Corbin, M.D. Kentucky School of Medicine, Louisville, 1892; a member of the American Medical Association, died at his home in Ellenboro, W. Va., October 23, aged 57.

Emmett Willin Price, M.D. University of Michigan, Ann Arbor, 1865; a member of the Ohio State Medical Association; died at his home in Kent, November 22, from uremia, aged 66.

John A. Washington, M.D. Vanderbilt University, Nashville, 1879; University of Nashville, 1880; of Murfreesboro, Tenn.; was thrown from a buggy, November 12, and instantly killed.

Placido Ferretti, M.D. College of Physicians and Surgeons, Boston, 1906, was found dead at his home in Worcester, November 16, from accidental poisoning by chloroform.

M. G. Parker, M.D. Rush Medical College, 1852; a member of the Indiana legislature in 1891; died at his home in Danville, November 12, from senile debility, aged 91.

George F. Marsden, M.D. Hahnemann Medical College, Philadelphia, 1866; died at his home in Red Bank, N. J., November 23, from disease of the stomach, aged 64.

John W. Webb, M.D. Jefferson Medical College, 1866; died at his home in Island Heights, N. J., November 13, aged 81.

Andrew M. Brown (license, Ga., 1898); died at his home in Jesup, November 3, after a surgical operation, aged 42.

Association News

HOW TO GO TO LOS ANGELES

The Railroad Routes to the Next Annual Session of the American Medical Association

The question of how to go to Los Angeles next June to the session of the American Medical Association is one which is interesting many members of the Association at this time. As is well known, there are three prominent routes to the far West: the southern route through Arizona, New Mexico, etc., taking in the Grand Canon; the central route through Colorado, the beautiful mountain scenery of the Rio Grande, etc., and the northern route, taking in Yellowstone Park and the magnificent Shasta trip along the mountain range of the Pacific slope.

The Committee on Transportation is now making arrangements for special trains for the use of members and their families who expect to attend the session. The committee is in touch with all the principal railroads and can make arrangements for special trains or cars as may be necessary from almost any point in the United States.

The chairman of the committee earnestly requests all those who expect to attend the session, particularly those living in the middle and eastern states, to communicate with him as soon as possible as to the route, southern, central, or northern, they desire to take west from Chicago. In this way, ample and satisfactory accommodations can be arranged for all. If any group of members from any city or territory will express their wishes to the committee, every effort will be made to secure special cars or train as may be necessary for their accommodation over the best route possible.

Applications for reservations on the special trains or on regular trains from Chicago west may now be filed with the Chairman of the Committee on Transportation, who will see that they are all properly taken care of.

M. L. Harris, Chairman,
Committee on Transportation.

100 State Street, Chicago.

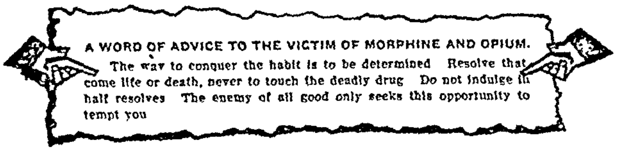
Pharmacology

A FRAUDULENT DRUG-HABIT "CURE"

Dr. J. W. Coblentz and His Compound Oxygen Association

Dr. J. W. Coblentz, of Ft. Wayne, Ind., has for years operated a mail-order drug habit "cure." In the early nineties Coblentz—who admits that he has been addicted to the alcohol and morphin habits—advertised extensively to cure persons addicted to the morphin habit. Of late years he has not advertised, but has relied on circular letters for what business he could get.

When the government commenced investigating the Compound Oxygen Association, one of the post-office inspectors wrote, under an assumed name, representing himself as a man 50 years old who had been addicted to the morphin habit for about six years, and who was using about 15 grains daily. Coblentz replied that he could be cured in four treatments, and that the cost of treatment would be $11. Advertising leaflets were also sent to this inspector in which it was stated that Coblentz' treatment was a "permanent and positive cure for the morphin habit." By implication the patient was led to believe that the "treatment" contained no morphin. For instance:



A WORD OF ADVICE TO THE VICTIM OF MORPHINE AND OPIUM.

The way to conquer the habit is to be determined Resolve that come life or death, never to touch the deadly drug Do not indulge in half resolves The enemy of all good only seeks this opportunity to tempt you

Fig. 1.—A photographic reproduction (reduced) of a paragraph in one of Coblentz' pamphlets. What can be thought of a man who urges the victims of the morphin habit "never to touch the deadly drug," while at the same time he is supplying "treatments" which were loaded with morphin?

> "Do not take every cure you see advertised, for how easy it is to disguise the drug under the garb of a new cure and beguile the poor, unsuspecting victim into the belief of being cured while all the time he is taking the drug under a different name."
>
> "The cure is simple and harmless."
>
> "I do not send out trial bottles. This is the method pursued by the medical shark. Half the time you receive your old drug (from whose clutches you are trying to escape) with the taste disguised."
>
> "I can truthfully say I can and will cure you if you will put your case in my hands."

The inspector sent $11 to Dr. Coblentz and received seven packages of medicines, which were analyzed by chemists in the Department of Agriculture.

No. 1.—A 16-ounce bottle of brown liquid, containing vegetable extractives, alcohol, water and morphin.

No. 2.—A 16-ounce bottle of brown liquid, having essentially the same composition as No. 1, except that there was some quinin salt in addition.

No. 3.—An 8-ounce bottle of liquid similar to that in Nos. 1 and 2, but with a smaller percentage of morphin.

No. 4.—A stomachic preparation, composed of water, alcohol, capsicum and morphin derivatives.

No. 5.—"Nervine Tablets;" chocolate-coated tablets of iron and quinin.

No. 6.—"Stomach Tablets;" sugar-coated tablets containing sodium bicarbonate, capsicum and strychnin.

No. 7.—"For the Bowels;" sugar-coated, laxative tablets containing aloes, cascara, ginger and licorice.

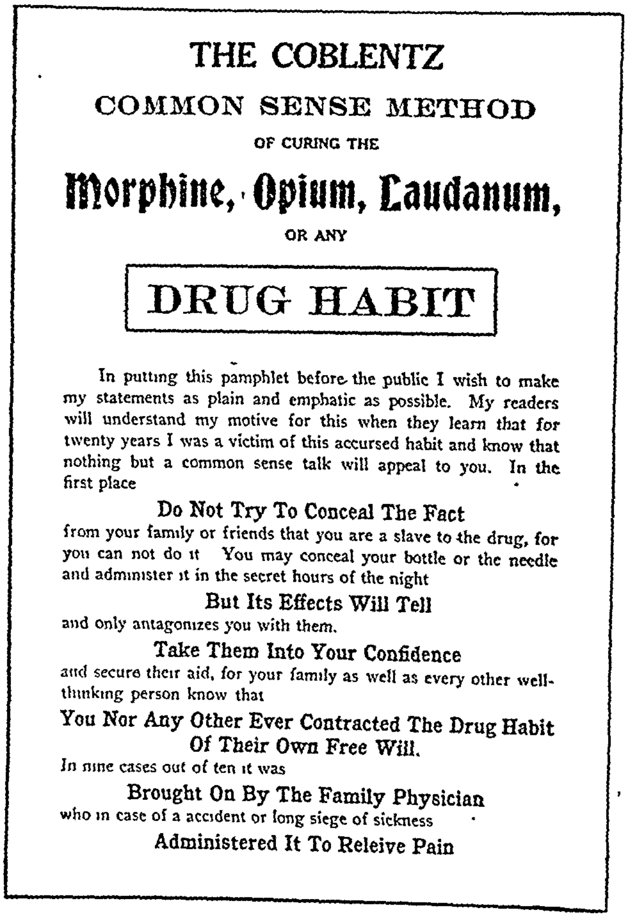
It was shown at the trial that the twenty-four-hour dose of the "treatment" sent by Dr. Coblentz to the person who was supposed to be using 15 grains of morphin daily, contained 20 grains of morphin!

The post-office inspector testified that he had interviewed Dr. Coblentz, and that Coblentz had told him that he was "treating" about twenty-five patients for the morphin habit, and that these patients had been under "treatment" for from five to twenty years! Coblentz also admitted that the medicine which he sold to patients for the cure of the morphin habit contained morphin in about the same amount as the patient was accustomed to using, and that this quantity was continued throughout. Coblentz is said further to have admitted that he had never really cured the appetite of anyone addicted to the morphin habit, but that the patients reached the point where he called them cured, but they had to keep up the use of the medicines. Correspondence was submitted at the trial which showed that one of Coblentz' patients had been taking the "cure" for fifteen years and was still taking it!

In view of all the evidence, the acting assistant attorney general summed up the case against Coblentz as follows:

> "The respondent is engaged in mailing letters and printed circulars to morphin habitués, and is soliciting and obtaining money from such persons by promising to cure them of that habit—that is to say, of the taste, desire and appetite for morphin, whereas, in truth, he does not intend to cure or try to cure such habit, but instead intends to furnish patients with a preparation containing substantially the same amount of morphin as they are accustomed to take, his purpose being to deceive such persons and to profit by their appetite for morphin and to get money out of them under false and fraudulent pretenses of furnishing them a cure for the habit, when he is simply furnishing the drug itself and not a cure.
>
> "On full consideration of the case, I find that Dr. J. W. Coblentz, under his own name and under the name of the Compound Oxygen Association, Fort Wayne, Ind., is engaged in carrying on a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. I recommend, therefore, that a fraud order be issued against him and said Association."

The order was issued.



THE COBLENTZ

COMMON SENSE METHOD

OF CURING THE

Morphine, Opium, Laudanum,

OR ANY

DRUG HABIT

In putting this pamphlet before the public I wish to make my statements as plain and emphatic as possible. My readers will understand my motive for this when they learn that for twenty years I was a victim of this accursed habit and know that nothing but a common sense talk will appeal to you. In the first place

Do Not Try To Conceal The Fact

from your family or friends that you are a slave to the drug, for you can not do it You may conceal your bottle or the needle and administer it in the secret hours of the night

But Its Effects Will Tell

and only antagonizes you with them.

Take Them Into Your Confidence

and secure their aid, for your family as well as every other well-thinking person know that

You Nor Any Other Ever Contracted The Drug Habit Of Their Own Free Will.

In nine cases out of ten it was

Brought On By The Family Physician

who in case of a accident or long siege of sickness

Administered It To Releive Pain

Fig. 2.—Photographic reproduction (reduced) of the first page of one of Coblentz' pamphlets. "The Coblentz Common Sense Method of Curing the Morphin . . . Habit" consisted in substituting a morphin mixture for the simple drug, thus creating a permanent customer for the "treatment!"

Robert C. Tuttle, M.D. Albany (N. Y.) Medical College, 1863; assistant surgeon in the U. S. Navy from 1862 to 1866; formerly of Rockland, N. Y., but for ten years past associated with his son at Roscoe, N. Y.; died at his home, November 10, from angina pectoris, aged 76.

Albert Berry Clanton, M.D. Jefferson Medical College, 1852; of Hattiesburg, Miss.; a lieutenant in the Mexican War, and a surgeon in the Confederate service during the Civil War; died at the home of his daughter in St. Louis, February 17, from pneumonia, aged 81.

George R. Millhouse, M.D. Columbus (Ohio) Medical College, 1878; a veteran of the Civil War; formerly of Allentown and Elida, Ohio, but for some time past a resident of Lima; died at the home of a niece in Piqua, Ohio, October 22, from heart disease, aged 70.

John Henry Shenk, M.D. University of Pennsylvania, 1861; a member of the Medical Society of the State of Pennsylvania; formerly school director and a member of the Lititz city council; died at his home, November 23, from uremia, aged 71.

John W. Cringan, M.D. University College of Medicine, Richmond, Va., 1901; of Arrington, Va.; a member of the American Medical Association; died on a Chesapeake and Ohio train at Ashcake, Va., November 22, from heart disease, aged 33.

John Thaddeus Carter, M.D. Cleveland University of Medicine and Surgery, 1890; professor of chemistry, toxicology, analysis, and physiology in Cleveland Medical College; died at his home in Cleveland, November 19, from nephritis, aged 48.

Harry S. Ford, M.D. McGill University, Montreal, 1904; of Vancouver, B. C.; died about November 10, from exposure, while lost in a forest near Jervis Inlet, 130 miles north of Vancouver, where he had been on a hunting trip, aged 30.

George Anthony Byrs, M.D. Rush Medical College, 1855; assistant surgeon of the One Hundred and Nineteenth Illinois Volunteer Infantry during the Civil War; died at his home in Clayton, Ill., October 25, from senile debility, aged 81.

Daniel O'Callaghan, M.D. Trinity College, Dublin, Ireland, 1871; Jefferson Medical College, 1882; for ten years a practitioner of London, and later of Kensington, Philadelphia; died at his home, November 13, from pneumonia, aged 71.

Herbert Charles Switzer, M.D. Detroit College of Medicine, 1902; a member of the American Medical Association; formerly of Gaines, Mich.; died at his home in Highland Park, Detroit, November 28, from pneumonia, aged 36.

James Hugh Bledsoe, M.D. Jefferson Medical College, 1891; formerly vice-president of the Marshall County (Tenn.) Medical Society; died at his home in Yokely, near Lynnville, Tenn., November 17, from pneumonia, aged 41.

James Pollock McCleery, M.D. Jefferson Medical College, 1857; surgeon of the Fifty-Sixth Pennsylvania Volunteer Infantry during the Civil War; died at his home in Milton, Pa., November 25, from paralysis, aged 78.

Robert Wallace Jakes, M.D. McGill University, Montreal, 1893; died at his home in San Francisco, November 20, from the effects of cyanid of potassium, believed to have been self-administered with suicidal intent, aged 40.

Sidney C. Burgess, M.D. University of Arkansas, Little Rock, 1886; president of the Polk County (Ark.) Board of Health; local surgeon at Russellville for the Missouri Pacific System; died at his home, November 12, aged 51.

William C. P. Butman, M.D. Albany (N. Y.) Medical College, 1854; assistant surgeon of the Third Missouri Volunteer Infantry throughout the Civil War; died at his home in Macon, Mo., November 12, aged 83.

Howard C. Brown, University College of Medicine, Richmond, Va., 1899; of Blythedale, Md.; while waiting for a train at Newark, Del., November 24, was struck by a train and instantly killed, aged 35.

William L. Miller, M.D. George Washington University, Washington, D. C., 1883; a member of the Medical Association of the District of Columbia; died at his home in Washington, November 20, aged 51.

Edmund D. Burwell, M.D. Louisville Medical College, 1875; a member of the Medical Association of the State of Alabama; died at his home in Huntsville, November 6, from intestinal miliary tuberculosis, aged 62.

Elam Bahr Mauger, M.D. Jefferson Medical College, 1875; a member of the Medical Society of the State of Pennsylvania; died at his home in Pottstown, November 20, from angina pectoris, aged 57.

John H. O'Bar, M.D. St. Louis College of Physicians and Surgeons, 1908; professor of fractures and dislocations in his alma mater; died in the O'Bar Sanitarium, St. Louis, November 22, from pneumonia, aged 39.

Leonard M. Mingos, M.D. Chicago Homeopathic Medical College, 1878; of Towanda, Pa.; died at his country home in Danville, N. J., November 3, from injuries received in a runaway accident, aged 56.

Homer L. Rochelle, M.D. Western Eclectic College of Medicine and Surgery, Kansas City, Kan., 1908; of Kansas City; died in Hot Springs, Ark., November 23, from nephritis, aged 48.

Martin Luther Corbin, M.D. Kentucky School of Medicine, Louisville, 1892; a member of the American Medical Association; died at his home in Ellenboro, W. Va., October 23, aged 57.

Emmett Willin Price, M.D. University of Michigan, Ann Arbor, 1865; a member of the Ohio State Medical Association; died at his home in Kent, November 22, from uremia, aged 66.

John A. Washington, M.D. Vanderbilt University, Nashville, 1879; University of Nashville, 1880; of Murfreesboro, Tenn.; was thrown from a buggy, November 12, and instantly killed.

Placido Ferretti, M.D. College of Physicians and Surgeons, Boston, 1906; was found dead at his home in Worcester, November 16, from accidental poisoning by chloroform.

M. G. Parker, M.D. Rush Medical College, 1852; a member of the Indiana legislature in 1891; died at his home in Danville, November 12, from senile debility, aged 91.

George F. Marsden, M.D. Hahnemann Medical College, Philadelphia, 1866; died at his home in Red Bank, N. J., November 23, from disease of the stomach, aged 64.

John W. Webb, M.D. Jefferson Medical College, 1866; died at his home in Island Heights, N. J., November 13, aged 81.

Andrew M. Brown (license, Ga., 1898); died at his home in Jesup, November 3, after a surgical operation, aged 42.

Association News

HOW TO GO TO LOS ANGELES

The Railroad Routes to the Next Annual Session of the American Medical Association

The question of how to go to Los Angeles next June to the session of the American Medical Association is one which is interesting many members of the Association at this time. As is well known, there are three prominent routes to the far West: the southern route through Arizona, New Mexico, etc., taking in the Grand Canon; the central route through Colorado, the beautiful mountain scenery of the Rio Grande, etc., and the northern route, taking in Yellowstone Park and the magnificent Shasta trip along the mountain range of the Pacific slope.

The Committee on Transportation is now making arrangements for special trains for the use of members and their families who expect to attend the session. The committee is in touch with all the principal railroads and can make arrangements for special trains or cars as may be necessary from almost any point in the United States.

The chairman of the committee earnestly requests all those who expect to attend the session, particularly those living in the middle and eastern states, to communicate with him as soon as possible as to the route, southern, central, or northern, they desire to take west from Chicago. In this way, ample and satisfactory accommodations can be arranged for all. If any group of members from any city or territory will express their wishes to the committee, every effort will be made to secure special cars or train as may be necessary for their accommodation over the best route possible.

Applications for reservations on the special trains or on regular trains from Chicago west may now be filed with the Chairman of the Committee on Transportation, who will see that they are all properly taken care of.

M. L. Harris, Chairman,
Committee on Transportation.
100 State Street, Chicago.

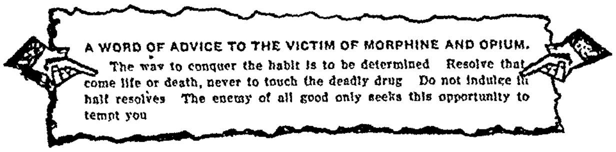
Pharmacology

A FRAUDULENT DRUG-HABIT "CURE"

Dr. J. W. Coblentz and His Compound Oxygen Association

Dr. J. W. Coblentz, of Ft. Wayne, Ind., has for years operated a mail-order drug habit "cure." In the early nineties Coblentz—who admits that he has been addicted to the alcohol and morphin habits—advertised extensively to cure persons addicted to the morphin habit. Of late years he has not advertised, but has relied on circular letters for what business he could get.

When the government commenced investigating the Compound Oxygen Association, one of the post-office inspectors wrote, under an assumed name, representing himself as a man 50 years old who had been addicted to the morphin habit for about six years, and who was using about 15 grains daily. Coblentz replied that he could be cured in four treatments, and that the cost of treatment would be $11. Advertising leaflets were also sent to this inspector in which it was stated that Coblentz' treatment was a "permanent and positive cure for the morphin habit." By implication the patient was led to believe that the "treatment" contained no morphin. For instance:



A WORD OF ADVICE TO THE VICTIM OF MORPHINE AND OPIUM.

The way to conquer the habit is to be determined Resolve that come life or death, never to touch the deadly drug Do not indulge in half resolves The enemy of all good only seeks this opportunity to tempt you

Fig. 1.—A photographic reproduction (reduced) of a paragraph in one of Coblentz' pamphlets. What can be thought of a man who urges the victims of the morphin habit "never to touch the deadly drug," while at the same time he is supplying "treatments" which were loaded with morphin?

> "Do not take every cure you see advertised, for how easy it is to disguise the drug under the garb of a new cure and beguile the poor, unsuspecting victim into the belief of being cured while all the time he is taking the drug under a different name."
>
> "The cure is simple and harmless."
>
> "I do not send out trial bottles. This is the method pursued by the medical shark. Half the time you receive your old drug (from whose clutches you are trying to escape) with the taste disguised."
>
> "I can truthfully say I can and will cure you if you will put your case in my hands."

The inspector sent $11 to Dr. Coblentz and received seven packages of medicines, which were analyzed by chemists in the Department of Agriculture.

No. 1.—A 16-ounce bottle of brown liquid, containing vegetable extractives, alcohol, water and morphin.

No. 2.—A 16-ounce bottle of brown liquid, having essentially the same composition as No. 1, except that there was some quinin salt in addition.

No. 3.—An 8-ounce bottle of liquid similar to that in Nos. 1 and 2, but with a smaller percentage of morphin.

No. 4.—A stomachic preparation, composed of water, alcohol, capsicum and morphin derivatives.

No. 5.—"Nervine Tablets;" chocolate-coated tablets of iron and quinin.

No. 6.—"Stomach Tablets;" sugar-coated tablets containing sodium bicarbonate, capsicum and strychnin.

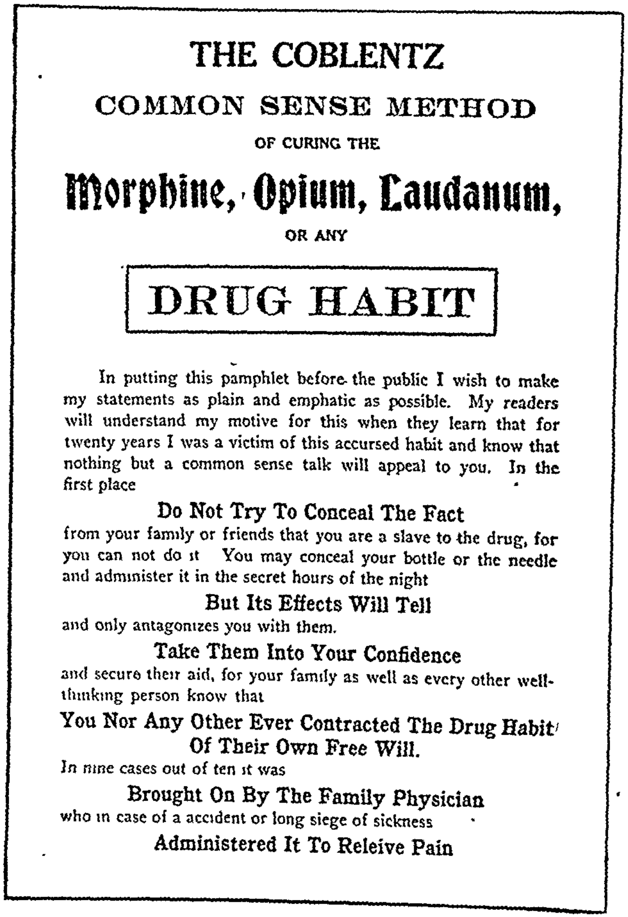
No. 7.—"For the Bowels;" sugar-coated, laxative tablets containing aloes, cascara, ginger and licorice.

It was shown at the trial that the twenty-four-hour dose of the "treatment" sent by Dr. Coblentz to the person who was supposed to be using 15 grains of morphin daily, contained 20 grains of morphin!

The post-office inspector testified that he had interviewed Dr. Coblentz, and that Coblentz had told him that he was "treating" about twenty-five patients for the morphin habit, and that these patients had been under "treatment" for from five to twenty years! Coblentz also admitted that the medicine which he sold to patients for the cure of the morphin habit *contained morphin* in about the same amount as the patient was *accustomed to using*, and that this quantity was continued throughout. Coblentz is said further to have admitted that he had never really cured the appetite of anyone addicted to the morphin habit, but that the patients reached the point where he called them cured, but they had to keep up the use of the medicines. Correspondence was submitted at the trial which showed that one of Coblentz' patients had been *taking* the "cure" for fifteen years and was still taking it!

In view of all the evidence, the acting assistant attorney general summed up the case against Coblentz as follows:

> "The respondent is engaged in mailing letters and printed circulars to morphin habitués, and is soliciting and obtaining money from such persons by promising to cure them of that habit—that is to say, of the taste, desire and appetite for morphin, whereas, in truth, he does not intend to cure or try to cure such habit, but instead intends to furnish patients with a *preparation* containing substantially the same amount of morphin as they are accustomed to take, his purpose being to deceive such persons and to profit by their appetite for morphin and to get money out of them under false and fraudulent pretenses of furnishing them a cure for the habit, when he is simply furnishing the drug itself and not a cure.
>
> "On full consideration of the case, I find that Dr. J. W. Coblentz, under his own name and under the name of the Compound Oxygen Association, Fort Wayne, Ind., is engaged in carrying on a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. I recommend, therefore, that a fraud order be issued against him and said Association."



THE COBLENTZ

COMMON SENSE METHOD

OF CURING THE

Morphine, Opium, Laudanum,

OR ANY

DRUG HABIT

In putting this pamphlet before the public I wish to make my statements as plain and emphatic as possible. My readers will understand my motive for this when they learn that for twenty years I was a victim of this accursed habit and know that nothing but a common sense talk will appeal to you. In the first place

Do Not Try To Conceal The Fact

from your family or friends that you are a slave to the drug, for you can not do it You may conceal your bottle or the needle and administer it in the secret hours of the night

But Its Effects Will Tell

and only antagonizes you with them.

Take Them Into Your Confidence

and secure their aid, for your family as well as every other well-thinking person know that

You Nor Any Other Ever Contracted The Drug Habit Of Their Own Free Will.

In nine cases out of ten it was

Brought On By The Family Physician

who in case of a accident or long siege of sickness

Administered It To Releive Pain

Fig. 2.—Photographic reproduction (reduced) of the first page of one of Coblentz' pamphlets. "The Coblentz Common Sense Method of Curing the Morphin . . . Habit" consisted in substituting a morphin mixture for the simple drug, thus creating a permanent customer for the "treatment!"

The order was issued.

Correspondence

Foreign Matter vs. the Treponema in Ink Methods

To the Editor:—In The Journal (Nov. 26, 1910, p. 1892), Dr. J. H. Barach gives an interesting criticism of the American India inks with special reference to foreign matter which may be present. His observations are good, especially as regards the "dried" preparations. I desire to add that these inks are not usually sterile, but often contain many microorganisms. Some of these methods, however, especially those in which the "wet" technic has been adopted, have been serving, exceedingly well, men who have found an office diagnosis necessary in many suspected cases of lues (*Arch. Diagnosis*, January, 1910). Can it be possible that this one communication must drive us back to the more tedious methods? Has any person claimed that these inks are free from extraneous material and their use without objection?

It may be well to note the following points:

1 No motions or other indications of life were observed in the "wavy fibers."

2 There is no mention that the turns of these lines or fibers were "close and regular" (Jordan's "General Bacteriology")

3 No emphasis was laid on the following important differentiation. "apparent rigidity vs. flexibility of spirals"

4 Stitt ("Practical Bacteriology") offers a test which should rule out "cracks" and which may be stated as follows "*Treponema pallidum*, . . . is characterized by its very geometric regularity in the spirals which are deeply cut, etc."

5. It is manifestly unfair to condemn any of these methods until their critic can say, "After a careful investigation, I cannot distinguish between these fibers and the true *Treponema pallidum*"

And with this last point in view, I believe that I have occasion to criticize the term "experienced microscopist" when used in reference to any ordinary clinical examination. Very often the fact is overlooked that, after all, many of our so called country doctors recognize cotton fibers, *Spirochæta refringens*, spirilla, cracks, etc, and dare not conscientiously term any and every wavy line, Schaudinn's specific microorganism. (It has been pointed out repeatedly, by the way, that the term "treponema" is preferable to "spirochete," and I believe that the latter term should be dropped, so far as the germ of syphilis is concerned) The physicians who are doing this work every day are not tyros but usually graduates of our best schools and received their training during the era of microscopy

Please to remember that a good Giemsa's stain requires two hours and is complicated and that the dark field attachment for the practitioner is an expensive asset. I do not believe that the article in question was intended to condemn the American inks, though it might be so interpreted by the man who has not yet observed their good points There is a tendency in medicine, however, to belittle anything which will make laboratory work possible to the man outside the college or hospital and an attempt—unconscious often, I believe—to convince him that he is not capable of recognizing so simple a thing as the urinary cast What is the result? Such examinations are left undone

Far be it from me to hold up any of the ink methods as model procedures Beauty is lacking The preparations do not in every portion show spirochetes Many bacteria are present in the ink and I believe that special inks should be made up for these examinations (let some chemical or optical company take up the suggestion) I have also observed many fibers and cracks But I have yet to find the *Treponema pallidum* in a bottle of Higgins' ink and I doubt if it occurs in others Surely, if it does, the war against the public drinking cup should be waged against another dangerous carrier of the modern black plague. These difficulties may be overlooked when we are considering diagnosis

Although I prefer to make these examinations from suspensions in warm, physiologic salt solution, I see no objection to studying these preparations after they have dried. It should be remembered however, that desiccation causes often, though not always, a loss of characteristic windings

In conclusion, permit me to say that the physician who has mastered his laboratory courses in microscopy may depend on the ink methods—he may still search for casts even though a few cotton fibers from his towel have fallen on his slide.

B. G. R. Williams, M.D., Paris, Ill.

Another Clean Medical Journal

To the Editor—An editorial in The Journal, Aug. 20, 1910, p 697, discusses the action of the *Gulf States Journal of Medicine and Surgery* in eliminating from its pages advertisements of such medicinal preparations as do not comply with the requirements of the Council on Pharmacy and Chemistry of the American Medical Association

May I call your attention to the fact that the *Cleveland Medical Journal* in November, 1909, announced a similar program and since then this rule has been observed in accepting new advertisements? Existing contracts, of course, had to be observed, and although practically all of the objectionable advertisements appeared for the last time in the issue of December, 1909, it was not until August, 1910, that the last one had disappeared.

Publicity of such facts as the above should certainly help in inducing other independent journals to adopt a similar censorship. William H. Weir, Editor, Cleveland, Ohio

[See Current Comment in this issue —Ed.]

Request for Specimens

To the Editor—May I ask through your columns for a few specimens? I need particularly a specimen of a tuberculous spine, a tuberculous sternoclavicular articulation and a tuberculous sacro-iliac articulation. If any of your readers, on removing one of these at autopsy will place it in a 2 per cent. dilution of liquor formaldehyde and will send it to me, I shall be glad to pay expressage, and shall be very grateful to him Leonard W. Ely, Metropolitan Bldg, Denver.

Coblentz Not With Medical Research Corporation

To the Editor:—In one of the summer numbers of The Journal (Aug. 6, 1910, p. 519), there appeared an article relative to the "Medical Research Corporation" ["International Encyclopedia of Ethical Non-Official Pharmaceuticals"] with which I was at that time connected as editor-in-chief. I call attention to the fact that I have severed my connection with this corporation V Coblentz, New York City.

Queries and Minor Notes

Anonymous Communications will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request

FINAL RESULTS IN VARICOSE ULCERS OF THE LEG

To the Editor—Please inform me what have been the final results in varicose ulcers of the leg on which an operation was performed by excision of veins and otherwise, and if a support like an elastic stocking must be worn afterward Nagroc

Answer—The final results of the treatment of varicose ulcers of the leg in which an operation such as excision of veins or otherwise has been performed depend largely on the nature of the operation done The ulcers are so intimately dependent on the varicose veins that the end results of the treatment of the latter represent equally well the end results of the treatment of the former

Perhaps the operation most frequently performed at the present time is the modified Trendelenburg operation, which consists in the excision of from 8 to 10 cm of the internal saphenous vein just below the saphenous opening This operation gives on an average about 50 per cent of objective cures and 75 per cent of subjective cures in cases followed from five to ten years The longer the elapsed time after the operation the greater the percentage of recurrences

The Schede operation, which consists of a circular incision around the leg just below the knee with the ligation and section of all the veins encountered, gives permanent good results in about 30 to 35 per cent of the cases.

Madelung's operation, or some modification of it, which consists in the more or less complete excision of the internal saphenous system of veins, is the most extensive operation and the least likely to be followed by a recurrence, but it is unnecessarily severe in a large percentage of the cases

Cases of varicose veins of the leg may be divided into three classes

1 Those in which the enlarged veins are all tributary to the internal saphenous and in which pressure on the internal saphenous after depleting the veins, prevents their refilling when the patient resumes the erect position

2 Those in which the enlarged veins communicate with the short or posterior saphenous in addition to the internal saphenous, and therefore pressure on the internal saphenous alone does not prevent the refilling of the veins

3 Those in which, in addition to the conditions found in Classes 1 and 2, there are communications between the superficial and deep set of veins by means of large sinuses, usually on the calf and inner surface of the leg, with the formation of large knots of veins in this region, and the veins refill even when pressure is made on both the internal and short saphenous veins

In Class 1 Trendelenburg's operation is usually sufficient, in Class 2 Trendelenburg's operation combined with excision of a section of the posterior saphenous In Class 3 there must also be added excision of the 'knots of veins with ligation and section of the communicating sinuses between the superficial and deep set of veins

If the cases be thus differentiated and the proper operation selected for each case, permanent results may be expected in from 90 to 95 per cent Of course, ulcers when present should receive proper treatment If they are large it is best to excise them completely and cover the surface with a Thiersch graft It is unnecessary to wear an elastic stocking after recovery, but the bandage should not be removed too soon after the patient gets up and around

TORTICOLLIS

To the Editor —Please give me references to articles on the subject of torticollis which have appeared during the past few years

R M Schley, Buffalo, N Y

Answer —The following are some of the articles which have appeared on the subject within the past two years

Bohm, M Etiology of Congenital Torticollis, *Berl klin Wchnschr*, Aug 9, 1909, abstr in The Journal, Sept 18, 1909, p 981

Broca, A Torticollis from Inflammatory Retraction of the Sternocleidomastoid Muscle, *Presse méd*, Sept 12, 1908

Kennedy, R Section of the Posterior Primary Divisions of the Upper Cervical Nerves in Spasmodic Torticollis, *Brit Med Jour*, Oct 3, 1908

Lister, T L Spasmodic Torticollis Following Chorea, *Lancet*, July 24, 1909

Newlin, A A Case of Torticollis, Probably Congenital, *Internat Clin*, 1907, series 17, iv, 255

Peters, A Asymmetry of Face and Skull in Relation to Torticollis, *Munchen med Wchnschr*, Aug 25, 1908

Rowlands, R P Treatment of Wry Neck by Lengthening the Sternomastoid, *Practitioner*, September, 1908, abstr in The Journal, Oct 3, 1908, p 1190

Weinstein, J Torticollis After Removal of Adenoid Vegetations, *Med Klin*, May 9, 1909

Williams, T A Facial Spasm and Tic, Torticollis and Treatment, *Month Cycl and Med Bull*, January, 1910

SEROTHERAPY OF TYPHOID FEVER

To the Editor —Where can I secure bacterial cultures or serums or antityphoid serum and literature on treatment with the serum?

F P Dorsey, Hartington, Neb

Answer —The bacterial cultures and antityphoid serum are described in New and Nonofficial Remedies and the names of manufacturers are there given There is little recent literature with reference to the use of the serums The following, dealing with antityphoid vaccination, may be referred to

Chantemesse, A, and Landouzy Discussion of Antityphoid Vaccination, *Bull de l'Acad de méd*, Feb 8, 1910, referred to in the Paris letter in The Journal, March 5, 1910, p 804

Russell, F F Antityphoid Vaccination, the Immediate Result of the Administration of 3,600 Doses, *Bull Johns Hopkins Hosp*, March, 1910, abstr in The Journal, April 16 1910, p 1337

Eckelman M M Vaccination Prophylaxis in Typhoid, *Jour. Indiana Med Assn*, April, 1910

Hartsock, F M Antityphoid Vaccination, Result of 1,100 Inoculations The Journal, June 25, 1910, p 2123

Gosman, G H R The Present Status of Typhoid Inoculation, The Journal, Oct 1, 1910, p 1169

STAINING SMEARS OF SPIROCHÆTA PALLIDA

To the Editor —Please describe an effective way to make the smears and stain the *Spirochæta pallida* to be used by the general practitioner

C A Manahan, Center Point, Iowa

Answer —The chancre or a skin lesion is cleansed with soap and water lightly curetted, the blood wiped off, and a thin smear made from the exuded serum Enlarged glands may be examined by aspirating a drop of serum from them with a hypodermic syringe The smear is fixed by drying in the air and then placing for an hour in absolute alcohol and stained for twenty four hours in diluted Giemsa mixture of 1 drop of Giemsa stain to 1 c c of the distilled water The organism stains a delicate violet purple color, while the nuclei of the leukocytes are of a deep blackish red The latter appearance shows that the specimen has been sufficiently stained The organisms are most numerous in moist papules and chancres (when the curettage is carried out at the edge of the lesion) In scrapings from roseola the search is frequently disappointing The organism should be distinguished from *Spirochæta refringens*, *Spirochæta dentium*, etc

SODIUM CITRATE IN FURUNCULOSIS

Since publishing the query of J L L in the issue of Nov 26, 1910 p 1911, in regard to Wright's method of using sodium citrate in furunculosis we have received a number of letters giving references to this method Nearly all refer to Crandon's work on 'Surgical After Treatment,' which explains Wright's method, or to an article by Crandon in the *Annals of Surgery*, October, 1910, abstracted in The Journal, Nov 5, 1910, p 1685, which also explains the Wright method of using sodium citrate solution in furunculosis, which we omitted in our former answer to the query.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Dec 3, 1910

Brown, Wilmont E, M R C, November 21, relieved from duty at Army General Hospital, Fort Bayard N Mex, and ordered to proceed to his home Lieutenant Brown will stand relieved from further active duty in the Medical Reserve Corps, to take effect on his arrival at his home

Weed, Frank W, captain, November 26, granted one month's leave of absence to take effect about Dec 15, 1910

Havelkampf, C W, lieutenant, November 22, reports departure on ten days leave of absence

Wolven, F Homer, D S, November 21, reported at Fort Casey, Wash, for temporary duty

Leslie Samuel H, D S, November 25, left Fort Robinson, Neb, en route to Fort McKenzie Wyo, for temporary duty

Usher, F M C, major, November 26, granted fourteen days' leave of absence

Stone, John H, major, November 25 granted four months' leave of absence with permission to go beyond the seas

Eber, Albert H, M R C, November 15, ordered to proceed from Fort Moultrie S C, to Fort Dade, Fla, for temporary duty, during the absence of First Lieut John H Hereford M R C

Jenkins, Frederick E, M R C, November 17, will report for duty with Co I Signal Corps, en route to Fort D A Russell, Wyo, on the completion of this duty to return to station at Fort Leavenworth Kan

Mason, George L, D S, November 16, reported for duty (temporary) at Fort Yellowstone, Wyo

Scott, H O D S, November 26, reported for duty at Fort Hamilton, N Y

Dougherty, James C, M R C, November 27, reported for temporary duty at Fort Huachuca, Ariz, left Fort Bliss, Texas, November 25, 1910

Miller, E W, captain November 28, granted leave of absence to and including Dec 25 1910

Brown, H L, captain, November 28, left Fort Morgan, Ala, on ten days' leave of absence

Candy Charles M, lieut col, December [illegible] is duties as chief surgeon, Department of Cal [illegible] he duties of medical superintendent, Army [illegible] an Francisco, relieving Lieut Col Henry S T [illegible]

Medical Corps, U. S. Navy

Changes for the week ended Dec 3, 1910

Hibbett, C T, medical director, commissioned medical director from Oct 7, 1910

Stone, E P, medical inspector, commissioned medical inspector from Aug 24 1910

Pickrell, G medical inspector, commissioned medical inspector from Oct 7, 1910

Trible, G B P A surgeon, commissioned passed assistant surgeon from June 27 1910

Hale, G D, and Bunker, C W O, P A surgeons, commissioned passed assistant suregons from Sept 21, 1910

Higgins, M E, P A surgeon commissioned passed assistant-surgeon from Oct 4, 1910

Stanley, A C, asst-surg, transferred to the retired list from Nov 23, 1910.

Ely, C. F., P. A. surgeon, detached from the *Wilmington* and ordered home.

Minter, J. M., asst.-surg., detached from the *Monterey* and ordered to the *Wilmington*

Bloedorn, W. A., asst.-surg., detached from the naval hospital, Canacao, P. I., and ordered to the *Monterey*.

Allen, D. G, asst.-surg., detached from the naval hospital, Canacao, P. I., and ordered to the *Elcana*.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Nov. 30, 1910.

White, J H., surgeon, leave of absence granted for ten days from Nov. 11, 1910, amended to read eight days from November 13.

McIntosh, W. P., surgeon, leave of absence granted Oct. 22, 1910, amended to read seventeen days from Nov. 11, 1910.

Grubbs, S B., P. A. surgeon, granted seven days' leave of absence from Nov. 28, 1910, on account of sickness.

Anderson, J. F, P. A. surgeon, directed to inspect the Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, N. Y.

Bahrenburg, L. P. H., P. A. surgeon, granted eleven days' leave of absence from Nov. 10, 1910, on account of sickness.

Frost, W. H., P A. surgeon, directed to rejoin station at Washington, D. C., stopping at Des Moines, Iowa, for conference with secretary of state board of health.

Hotchkiss, S. C., asst.-surgeon, relieved from duty on the Revenue Cutter *Bear* and directed to report to the director of the Hygienic Laboratory.

Atiles, P. del Valle, A. A. surgeon, granted thirty days' leave of absence from Dec. 1, 1910.

Gustetter, A L., A A. surgeon, granted fifteen days' leave of absence from Dec 9, 1910.

Tarbell, B C., A. A. surgeon, granted thirty days' leave of absence from Dec. 1, 1910.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fifth Month—First Weekly Meeting

General Subject for the Month: Diseases of the Skin

ANATOMY OF THE SKIN

EPIDERMIS: Stratum corneum, stratum lucidum, stratum granulosum, rete malpighii.

CORIUM: Pars papillaris, pars reticularis.

SUBCUTANEOUS LAYER: Blood-vessels. Lymphatics. Nerves. Muscles. Glands. Appendages.

PHYSIOLOGY OF THE SKIN

Protective function. Heat regulation, tactile and pain sensations, respiratory and secretory functions, elimination.

GENERAL SYMPTOMATOLOGY

SUBJECTIVE SYMPTOMS: Itching, burning, tingling, pain, tenderness, etc.

OBJECTIVE SYMPTOMS: Primary lesions: Macules, papules, vesicles, blebs, pustules, wheals, tubercles, tumors. Secondary lesions. Scales, crusts, excoriations, fissures, ulcers, scars, pigmentations.

TREATMENT IN GENERAL

HYGIENE: Diet.

MEDICINAL TREATMENT: General tonics, aperients, gastrointestinal antiseptics, diuretics, alteratives, animal extracts, germicides, antipruritics, vasoconstrictors.

LOCAL TREATMENT: Baths, soap, dusting-powders, lotions, ointments, pastes, oils, fixed dressings. Antipruritics, parasiticides, caustics. Mechanical measures.

REFERENCE BOOKS FOR THE FIFTH MONTH

Works on "Diseases of the Skin," by Stelwagon, Hyde, Shoemaker and Crocker.

Pusey: Principles and Practice of Dermatology.
Kaposi: Pathology and Treatment of Diseases of the Skin.
Morrow: Genitourinary Diseases, Syphilology and Dermatology.
Fox: Diseases of the Skin (Photographic Atlas).

Miscellany

Tuberculosis in the Philippine Islands.—It is the opinion held by most persons who have not lived in the tropics that tuberculosis is less prevalent there than in the temperate zones. This, however, according to Dr. Isaac W. Brewer (*Journal of the Outdoor Life*, September, 1910) is not true of the Philippines. Brewer states that the deaths in those islands from tuberculosis outside of Manila in 1907 was 210 per hundred thousand as against 172 in the registration area of the United States, for instance, and that the death-rate from this cause in Manila during 1908 was 486 per hundred thousand as against 89 for the city of St. Paul, Minn. He says that if there is any virtue in sunshine and fresh air there should be but little tuberculosis in those islands, as the climate is rarely so severe even in the rainy season as to compel the inhabitants to keep their houses closed. The habits of the Filipino, however, are such that fresh air is usually lacking in his residence. The rarity of tuberculosis among cattle in the Philippines indicates that the climate itself cannot be responsible for this disease among the natives. Dr. Brewer's study shows that the same causes are operative as apply elsewhere—bad hygienic surroundings, poor food, and improper clothing. The houses of even the better classes are lacking in ventilation and are kept religiously closed during the day to exclude the heat and also at night because of the belief that the night air will cause fever. An actual count of 200 houses in Manila at midnight showed that less than 25 per cent. had the street windows open, and in many there were no windows in the bedrooms. It is not uncommon to find horses and other animals kept in the lower floors of the best houses in Manila. The poorer natives in both the cities and the provinces live in thatched cottages which seem to be well ventilated, but on closer examination it is found that the windows are closed during the greater part of the day and all night; the space beneath the houses is occupied by hogs, goats, and cattle, and beneath the kitchen will be a filthy hog-wallow into which is thrown the refuse from the house. The Filipino is a great chewer and spitter and he expectorates wherever most convenient. There is also a habit of exchanging partially smoked cigarettes and cigars which undoubtedly is a means of conveying the infection of tuberculosis. In addition, over 90 per cent. of the natives are the hosts of intestinal parasites, which, while they may cause no special symptoms in themselves, predispose their host to other infections, particularly tuberculosis. The average native is poorly nourished, living mostly on rice and fish, with occasionally pork and rarely beef, together with a few roots, fruits and green vegetables. The clothing is mostly cotton, which in the rainy season remains damp; shivering natives are a common sight. Except in the larger towns there is a great lack of medical attention, and indeed few towns could support a physician. Brewer believes that the inhabitants would readily avail themselves of hospitals or dispensaries and that much good could be accomplished by the American government by the establishment of such institutions in the small country towns. He thinks that an enthusiastic physician with a few good trained nurses and a supply of drugs could accomplish wonders. An active campaign of education must be instituted, but the methods adopted must be different from those adopted in other countries because the people are not so far advanced in their knowledge of hygiene.

Influenzal Meningitis.—Influenzal meningitis is a rare disease, chiefly restricted to young children, and having a mortality of 90 per cent. About 40 cases have been reported in the literature but it is probably more common than these reports indicate. David J. Davis (*Tr. Chicago Path. Soc.*, June, 1910) reports seven cases of influenzal meningitis which were recognized in Chicago in a little over a year, all resulting fatally, and in duration varying from three to fourteen days. All the patients were infants, the oldest being 13 months and the youngest five days. A definite history of "cold" preceding the meningeal trouble was obtained in four cases. Temperature as a rule was variable and ranged from 100 to 105 F. or higher. Petechial hemorrhages in the skin occurred in one case and herpes labialis in one. Eye symptoms as a rule were present and also marked retraction of the head and rigidity of the back and limbs. Lumbar puncture was made in four cases, and in all turbid fluid under pressure was obtained, which contained many leukocytes, the polynuclear cells predominating (usually about 80 per cent.). Five of the cases were examined post-mortem. An abundant highly purulent greenish yellow friable leptomeningeal exudate was present in four; in the remaining case, in which the patient died on the third day, the exudate was scant and not characteristic. As a rule the exudate was very abundant at the base and over the frontal lobes. In one case there was an extensive hemorrhagic serofibrinous exudate lining the dura, and in one case a large cerebral abscess occurred in the right hemisphere, and extensive acute softening occurred in the cortex of the opposite hemisphere. Internal hydrocephalus existed in this case also. Acute bronchitis was present in four and bronchopneumonia in three cases Acute rhinitis was found in three, one showing extensive necrosis of the entire nasal mucosa involving the cribriform plate. Bilateral otitis media occurred once and acute gastro-enteritis once. In all cases acute degeneration of the various organs was evident. The influenza bacillus was isolated in practically pure culture from the meningeal exudate and cerebrospinal fluid in all cases. In two it was found pure in the heart's blood; in one in the peritoneal fluid, and in one in the pericardial fluid. In three cases it occurred mixed with streptococci in the bronchial secretion, and once it was grown from the surface of the nasal mucosa. The atrium of infection in four cases was in all probability the upper respiratory passages, in two of which the infection undoubtedly penetrated the cribriform plate. The serum obtained from the heart's blood in four cases failed to agglutinate influenza bacilli. The bacilli are pathogenic for guinea-pigs in moderate doses, and are about equal in this respect to influenza bacilli isolated from other sources. Morphologically and culturally they are identical with Pfeiffer's bacillus, all being strictly hemophilic and showing the property of symbiosis The grouping of these cases is interesting. The occurrence of the disease in twins beginning on the same day is suggestive of a common source of infection, but this could not be determined. Two patients came from a small institution for children in which an epidemic of 'colds" had existed for several weeks. The children were all constantly in intimate contact with each other. The second of these patients developed the disease about four weeks after the first was taken ill, or about two weeks after her death. Three of the cases developed in institutions They did not occur in the poorer parts of the city. Except two, which developed in October, all the cases occurred in the winter months A general influenza epidemic was not raging during this period.

Utero Ovarian Asthma.—E. Percepied cites a number of instances in which reflex action from the genital organs was responsible for the development of asthma; in fully 40 per cent. of his female patients with asthma the attacks came on with or just before menstruation In 3 of the patients in this class the attack always preceded the menses by 4 days; in one patient the attack followed the period. In one case the patient had a cough during menstruation and in the course of years this cough finally became actual asthma Among his 381 asthmatic female patients the asthma came on at the menopause in 26 and 12 others had then spasmodic coryza, or a wheezing bronchial affection without true asthma. In 7 cases there was great aggravation of the asthma during the menopause. In 8 cases the asthma came on for the first time during a pregnancy or the puerperium and recurred in some of the patients during later pregnancies, while 2 other patients were relieved during pregnancy. Tentative treatment with ovarian or thyroid extract may be instituted, he says, though he never observed any improvement from ovarian treatment in his climacteric cases. The tendency to respiratory troubles in general should be combated and this is the main factor in treatment His article on the subject appeared in the *Annales de la Soc. Méd.-chir. de Liége*, 1910, XLIX, 126.

Mortality from Infectious Diseases in Europe.—F. Loeb at Munich has compared the vital statistics of various European cities and tabulated the condensed findings in the *Munchener medizinische Wochenschrift*, Nov. 8, 1910, as follows: For each 100,000 inhabitants the highest mortality was for

Small pox	336.4 at Marseilles,	35.6 at Moscow
Typhoid	81.7 at Marseilles,	58.5 at Athens
Diphtheria and croup	37.0 at Dresden,	33.9 at Moscow
Measles	101.1 at Rome,	45.9 at Vienna
Whooping cough	37.3 at Copenhagen,	32.2 at Edinburgh
Scarlet fever	45.4 at Warsaw,	39.6 at Moscow
Tuberculosis of lungs and other organs	631.2 at Prague,	
Pulmonary tuberculosis	397.0 at Paris,	337.8 at Lyons
Pulmonary tuberculosis and other respiratory diseases	793.1 at Moscow,	718.5 at Lyons
Pneumonia	303.5 at Warsaw,	238.7 at Brussels
Malignant disease	228.7 at Prague,	157.6 at Lyons

The mortality from pulmonary tuberculosis was:

In seventy two cities of France with population over 30,000	325.7
In twelve cities of Greece with population over 10,000	276.5
In forty nine cities of Spain	238.3
In Switzerland	172.1
In German Empire	159.2
In the Netherlands	120.7
In England and Wales	111.7
In Belgium	101.3

In the 350 largest towns in the German Empire from tuberculosis of lungs and other organs the mortality was 192.4. From "Tuberculosis of Other Organs," Switzerland, 78.5; 49 cities of Spain, 65.2, 72 cities of France, 61.4; England and Wales, 46.9; Germany, 22.5 The mortality from diphtheria and croup for 100,000 inhabitants was:

In Russia	59.1	In German Empire	22.9
In 49 cities of Spain	19.1	In 72 cities of France	9.0
In the Netherlands	8.2		

The mortality from scarlet fever for 100,000 inhabitants was:

In Russia	111.0	In Greece	20.0
In German Empire	19.1	In the Netherlands	5.3

The mortality from small-pox for 100,000 inhabitants was:

In Russia	51.6
In seventy two cities of France with population over 30,000	27.1
In forty nine cities of Spain	16.0
In the German Empire	0.1

British Comment on Medical Practice in the United States.—The laws regulating the practice of medicine in the various states and territories of the United States of America differ to a considerable extent in detail. In spirit, however, they are beginning to assume that uniformity which all medical reformers must desire for them. It has long been pointed out that one of the most open doors to abuse of medical practice in the United States was the fact that while in some states an excellent medical curriculum was required before admission to legal practice, in other states but little scientific training was exacted and freedom to practice was extended to dangerous forms of quackery. This position of affairs had its origin, of course, in the evolution of the United States, certain divisions of the country being in the forefront of civilization, while others were, to say the least, in a rudimentary plight; but of late a great process of leveling-up has been witnessed. The progress of the United States is in no way better shown than in the fact that throughout its vast length and breadth there is now an attempt to secure for the people of the country adequate medical treatment based on scientific grounds. . . . We must continue to warn the British medical man desiring to practice his profession in the United States that in all the more enviable centers he will find a vast number, almost a plethora, of medical men, the great proportion of whom have been thoroughly well educated and trained He must remember also that in the more important states, generally speaking, although the remuneration may rule high, the expense of living is proportionate He will understand that the less highly the state is developed the more easy will it be for him to obtain a footing, but the less pleasant in all probability will be his professional career.—*Lancet* (London), August 27.

State Boards of Registration

COMING EXAMINATIONS

Delaware: Regular, Dover, December 13-15; Homeopathic, Wilmington, December 13-15. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

Kentucky: Louisville, December 15-17. Sec., Dr. J. N. McCormack, Bowling Green.

Maryland: 1211 Cathedral St., Baltimore, December 13-16. Sec., Dr. J. McPherson Scott, Hagerstown.

Virginia: Lynchburg, Dec. 20-23. Sec., Dr. R. S. Martin, Stuart.

Iowa Adopts Concentration Method

The State University of Iowa College of Medicine has adopted the concentration method of teaching for the courses of the first two years. It is the Harvard plan modified to a considerable extent. The arrangement of the work and the number of class-room hours per week in each subject are shown in the following schedule:

	—Class-Room Hours per Week—			
	First Year		Second Year	
Subject	1st Sem.	2d Sem.	1st Sem.	2d Sem.
Anatomy, histol. and embryol..	27	19	9	—
Physical and organic chem..	4	2	—	—
Physiologic chemistry	—	—	4	6
Physiology	—	10	8	—
Pharmacy	1	—	—	—
Materia medica	—	2	2	—
Pharmacology	—	—	—	4
Bacteriology	—	—	10	—
Pathology	—	—	—	18
Hygiene and dietetics	—	—	—	4
Physical diagnosis	—	—	—	2
Total class-room hrs. per week	32	33	33	34

Since this method applies only to the freshman class this year, it is too early to make any definite statements, but thus far the results are very satisfactory.

Standard of Preliminary Education in Iowa

Dr. G. H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports that at a recent meeting the following schedule was adopted, giving the minimum entrance requirements which must be enforced by all colleges after Jan. 1, 1911, in order to be in good standing:

Sec. 1. The college must require of each student a creditable certificate of good moral character, signed by at least two physicians in good standing in the state from which the applicant comes.

Sec. 2. The minimum scholastic attainments to be required of each student for admission to the medical school must be a four-year course in a fully accredited* high school, academy or seminary in which at least two years of foreign language is required, and, in addition thereto, two full years of college work in an accredited college, which shall include at least ten semester-hours† of chemistry, ten of physics (or six, if one year in the subject was done in high school), six of biology, and ten of foreign language. The foreign language taken in college must include enough Latin to make the total Latin taken in high school and college together equal to two years' work in that subject.

Sec. 3. The above requirements are hereby adopted and are in full force and effect on and after January 1, 1911; and thereafter any medical or osteopathic college requiring a lesser standard of qualifications will not be considered in good standing with the Iowa State Board of Medical Examiners.

Oregon July Report

Dr. E. B. McDaniel, secretary of the Oregon State Board of Medical Examiners, reports the written examination held at Portland, July 5-7, 1910. The number of subjects examined in was 15; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 106, of whom 58 passed, including 8 osteopaths and 1 non-graduate and 48 failed, including 6 osteopaths. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Denver and Gross College of Medicine	(1909)	77.8
Yale Medical School	(1909)	75

Facultad de Medicine, Guatemala	(1891)	58.5

The following questions were asked:

CHEMISTRY

1. Define chemistry, including its two principal divisions, and their subdivisions. 2. Name and describe the crystals that may be found in acid urine and in alkaline urine. 3. Differentiate an alkaloid from a glucosid, defining each, and name three of each used in medicine. 4. Write a prescription wherein a chemical reaction resulting in a new end-product is produced, and name the end-product. 5. Write two prescriptions which, if carelessly compounded, would result in explosions, and state what chemical action occurs to produce the explosion in each case. 6. Give a chemical test for arsenic. Name chemical antidote. State how it is prepared. 7. Give a simple test for mineral impurities in drinking water; also for vegetable impurities in drinking water. 8. Define resin. Name five used in medicine.

PHYSIOLOGY

1. In which part of the alimentary tract does the greatest amount of absorption of foods take place? Of water? Is absorption a physical or vital process? 2. State concisely but in detail what happens to proteins, carbohydrates, and fats, after absorption. 3. Give proportion of blood to total body weight. In sudden hemorrhage in a healthy individual, what proportion of blood to the body weight may be lost without proving fatal? 4. What are the principal heat-producing tissues? Mention the circumstances which cause variation in temperature. 5. Where are the following centers: (*a*) respiratory, (*b*) micturition, (*c*) vasomotor, (*d*) visual, (*e*) auditory? 6. What are the important parts of the eye physiologically? 7. Name and specifically state the functions of the tenth cranial nerve. 8. Define diapedesis, hemolysis, osmosis, zymogen, colostrum, cholesterin.

---

* By an "accredited" high school, academy or seminary is meant one that has been inspected and fully accredited by the state university of the state in which it is located; or, in other words, a high school, academy or seminary, a diploma from which would admit the holder to the College of Liberal Arts of the University of Iowa without examination. The matriculation examination for entrance on the study of medicine must be conducted by one especially qualified and not by any member of the medical faculty. Any disputes arising as to an accredited school or as to the standard of examination for applicants for matriculation shall be referred for settlement to the Iowa State Inspector of Schools.

† By "semester-hour" is meant a subject taken for one hour a week during one semester. This equals from sixteen to eighteen hours of didactic class-room work or thirty-two to thirty-six or more hours of laboratory work.

HISTOLOGY

1. What is a gland? Name its forms. Of what does the secreting portion of all glands consist? 2. Define and classify epithelial tissue. 3. Of what do ganglia consist? Name kinds of ganglia and state what covers outer surface. 4. State specifically where you find (*a*) Meissner's plexus, (*b*) Auerbach's plexus, (*c*) crypts of Lieberkuhn, (*d*) Bowman's capsule, (*e*) Heller's plexus.

PATHOLOGY

1. Differentiate the blood of pernicious anemia from that of myelogenous leukemia. 2. Give pathology of follicular tonsillitis in detail. 3. Give pathologic changes taking place in chronic myocarditis. 4. Give pathologic anatomy of simple catarrhal broncho pneumonia.

NERVOUS DISEASES

1. Give the etiology and diagnosis of sciatic neuralgia (sciatica). 2. Give the differential diagnosis between hemorrhage into the brain substance and ventricular hemorrhage and meningeal hemorrhage. 3. Give symptoms of bulbar paralysis. 4. Describe in detail the "rest cure" treatment of neurasthenia.

OBSTETRICS

1. What is the difference in measurements between the anteroposterior diameter of the superior strait and the oblique diameter at the same point? 2. (*a*) Describe the process of ovulation. (*b*) What influence, if any, has ovulation on the function of menstruation? What is the source of blood-supply appearing in menstruation? 3. Describe the process of gestation from conception to parturition. 4. What is the cause of pernicious vomiting in pregnancy? Give treatment. 5. Define hourglass contraction of the uterus. (*b*) What is the danger to the mother in this complication? (*c*) Give treatment. 6. (*a*) In case of laceration of the perineum in labor, when and how would you repair it? (*b*) Describe after-treatment. 7. Describe the change taking place in the circulation of the child coincident with birth. 8. Describe your management of a case of ante-partum eclampsia at full term.

DIAGNOSIS

1. Give diagnosis of both acute and chronic appendicitis. 2. Diagnose hepatic colic. 3. Give differential diagnosis of diphtheria and acute follicular tonsillitis. 4. Diagnose acute inflammatory rheumatism. 5. Diagnose cirrhosis or chronic atrophy of the liver. 6. Give diagnosis of cerebrospinal neurasthenia. 7. Diagnosticate diabetes mellitus. 8. Diagnose anterior poliomyelitis.

GYNECOLOGY

1. Give etiology and symptoms of obstructive dysmenorrhea. 2. What are the (non-surgical) methods of replacing a retroverted or retroflexed uterus when fixed by adhesions? 3. What is the treatment—(*a*) prophylactic and (*b*) curative—of chronic metritis? 4. Give symptoms and diagnosis of ectopic gestation. 5. Describe the method and principal points to be noted in performing bimanual examination per vaginum. 6. What are the causes and treatment of pelvic peritonitis? 7. How does gonorrheal vaginitis differ from the simple catarrhal? 8. What are the principal displacements of the uterus? Describe two of them.

PRACTICE OF MEDICINE

1. Differentiate the crepitant rale and the subcrepitant rale, and give the clinical significance of each. 2. Describe the natural heart-sounds. 3. Give the physical signs of pleuritic effusion. 4. What are the physical signs of aortic regurgitation? 5. Give the period of incubation and of eruption of the exanthemata. 6. Give the symptoms and treatment of tetanus. 7. Give the etiology, symptoms and treatment of gastrointestinal catarrh of infancy and childhood. 8. What are the symptoms of acute parenchymatous nephritis?

EYE AND EAR

1. What are the causes of ptosis and the remedial measures employed? 2. What are the pathologic conditions in gonorrheal ophthalmia and give the treatment of gonorrheal ophthalmia? 3. Where should the opening be made in order to reach the antrum in a case of abscess of the middle ear? 4. Give the etiology, diagnosis and treatment of acute otitis media.

SURGERY

1. What arteries, muscles and nerves would be severed in amputation at the middle third of the humerus? 2. Describe the symptoms and give the treatment of hemorrhage from the middle meningeal artery. 3. Name and describe the different varieties of fracture. 4. Describe the several varieties of club-foot. 5. Relate the causes of intestinal obstruction. 6. Describe hypospadias, epispadias, phimosis and paraphimosis. 7. Name the different varieties of benign tumors. 8. What are the causes and the treatment of pelvic peritonitis?

DISEASES OF CHILDREN

1. Describe the symptoms of empyema and give treatment. 2. Describe intussusception and volvulus; give treatment of both conditions. 3. Name the different varieties of stomatitis. 4. Describe chorea and give treatment of chorea minor. 5. Give symptoms of otitis media and treatment of same. 6. Describe the eruption of scarlet fever, measles and syphilis, and give the diagnostic points of each. 7. Write a prescription for a child 5 years old suffering from *tænia solium*. 8. Give symptoms of acute anterior poliomyelitis.

MATERIA MEDICA AND THERAPEUTICS (HOMEOPATHIC)

1. Name three remedies useful in suppurative processes, with indications for the use of each. 2. Name the so-called "twelve tissue remedies." 3. Name the tissue remedies most useful in mental states and affections. 4. Name the tissue remedies most useful in simple fevers. 5. Compare respiratory symptoms of bryonia, phosphorous and antimonium tartaricum. 6. Give the mental symptoms of cannabis indica and ignatia. 7. Cinchona: give its common name; form of preparation used; sphere of action. 8. Arsenicum album: write as much as you can about this drug and its action, using not more than twenty lines, or 100 to 125 words.

MATERIA MEDICA AND THERAPEUTICS

1 Define: (a) materia medica, (b) therapeutics, (c) minimum dose, (d) maximum dose, (e) toxic dose, (f) lethal dose. 2. How much silver nitrate would you use to make 2 ounces of 10 per cent. solution of the same in water and show your mathematical work? 3. How would you diagnose and state briefly how you would treat poisoning by: (a) hydrocyanic acid, (b) arsenic, (c) strychnin, (d) belladonna, (e) carbolic acid? 4. Iodin: (a) give chief source and brief description of same; (b) name five preparations used in medicine, containing iodin free or in combination: (c) name three conditions in which iodid or its salts are indicated. 5. Salol: (a) give official name; (b) give dose; (c) describe briefly its action on the stomach and small intestines. 6. Give the physiologic action of veratrum and aconite and name diseases in which they are useful, stating dose. 7. Name two of the most important remedies used in the treatment of syphilis, the stages in which indicated and give method of administration. 8. Describe the treatment of gonorrhea in the female.

Louisiana October Report

Dr. A. B. Brown, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, October 18-19, 1910. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 31, of whom 11 passed and 20 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Alabama	(1910)	75
University of Louisville	(1910)	78.1, 80.1, 87.8
Tulane University of Louisiana	(1910)	76.9, 79.3, 85.9
Baltimore Medical College	(1907)	80.2

Minnesota October Report

Dr. W. S. Fullerton, Secretary of the Minnesota State Board of Medical Examiners, reports the written examination held at Minneapolis, October 4-7, 1910. The number of subjects examined in was ten; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 21, of whom 17 passed and 4 failed. Eleven candidates were licensed through reciprocity. The following colleges were represented:

Book Notices

The Practice of Medicine. A Guide to the Nature, Discrimination and Management of Disease. By A. O. J. Kelly, M. D., Assistant Professor of Medicine in the University of Pennsylvania and Assistant Physician to the University Hospital, Philadelphia. Cloth. Price, $4.75 net. Pp. 945, with illustrations. Philadelphia: Lea & Febiger, 1910.

The tremendous changes in our conceptions of pathologic as well as physiologic processes, and consequently in treatment, are reflected in this new book. In the first chapter, on infectious diseases, is condensed in a brief space reference to all the work of the last ten or fifteen years in the blood and secretions—everything from antigens, antibodies and agglutinins, hormones and internal secretions to lysins and the toxins of the zooparasites. The student and the junior practitioner, for whom this work is intended, unless exceptionally well taught and attentive in his college course, and unless conversant with current medical literature, must indeed be bewildered by all this wealth of reference to the "newer pathology," but it illustrates the increasing complexity of medicine.

In looking over the classification of diseases one is impressed with the increased number of and the increased space given to the zooparasitic infections—the protozoan and metazoan infections—by the formidable list of thirty-seven diseases which the author has classified under the head of "Infections of Unknown or Doubtful Etiology," and by the list of twelve "Nervous Diseases of Functional or Unknown Nature." So that with all the advance that has been made, the ground seems merely scratched and the investigator still has an immense and rich field before him for cultivation.

Noteworthy also is the increasing number of diseases or conditions described under new separate heads, or described under new designations, in connection with certain systems. Under diseases of the circulatory system, for instance, we have weak or insufficient heart, overstrained or irritable heart, the infectious febrile heart, the fibroid heart and tumors and parasites of the heart; multiple serositis under diseases of the peritoneum, perinephritis and paranephritis under diseases of the urinary system, etc. And it may be added that there are quite a number of conditions described at length, with a lengthy probable symptomatology, which the author admits can be diagnosed only at autopsy. The discussion of pathologic physiology at the beginning of each new section is a good feature of the book.

The author advocates the tub bath and milk diet in typhoid fever, and says that he has never seen good results from a generous diet. Preventive inoculation in typhoid, he believes, is of doubtful value, and the serum treatment has not commended itself to the profession. The treatment of bacterial infections by bacterins is approved, and pneumonia patients should have open air or at least fresh-air treatment throughout in preference to "canned" oxygen *in extremis*. He calls attention to the revised conception of diphtheria, to the effect that it is often more than an infection by the Klebs-Loeffler bacillus, and calls the microorganism of cholera by the rather unusual designation of *Microspira comma*. Uncinariasis, he states, exists in Florida in 90 per cent. of the population, and in subtropical countries and in Germany, but he says nothing about its prevalence in other parts of the United States. The lavish use of parentheses throughout the text is jarring on the reader, and detracts from an easy, readable style. The foundation of a good, modern work is here, and when it has passed through the refining fire of a revision, it will take its place among the standard works on the practice of medicine.

Clinical Obstetrics. By Robert Jardine, M.D., Edin., Professor of Midwifery in St. Mungo's College, Glasgow. Third Edition. Cloth. Price, $6.50 net. Pp. 716, with 112 illustrations. New York: William Wood & Co., 1910.

Professor Jardine's book differs from most other books on obstetrics in that a considerable part of the space is given to the relation of cases illustrative of nearly every complication of pregnancy, labor and the puerperium. The term "clinical obstetrics" is therefore appropriate. The descriptions of the normal and pathologic conditions are nevertheless clear and fairly complete although sometimes brief while the symptoms, diagnosis and treatment are sufficiently given and make the book a satisfactory text-book for students. In this edition considerable new matter has been added, especially on the subject of neuritis, pyelitis, acute yellow atrophy of the liver, eclampsia, etc., as well as the reports of fifty new cases. There are now thirty-two cases of eclampsia reported, and a number of rare complications. The illustrations are well selected and well made.

This way of writing a book on obstetrics, which is essentially the same as that followed by Smellie, the great pioneer English obstetrician, has distinct advantages. First, it assures the reader that the author knows whereof he speaks. One may know at the beginning that the book is not simply another compilation. Then, the conclusions reached by the writer can be judged, for the material on which they are based is presented with the conclusions. The chief criticism of Jardine's method of presenting his cases is that when a number are reported to illustrate a complication, as in eclampsia, he does not classify the cases and compare them in a brief and clear summary. This makes it difficult for the reader to obtain a comprehensive view of the cases and form a judgment of the results without a considerable amount of work that might have been avoided had the author followed the method of study and comparison that is adopted by the directors of clinics.

Some objections might be raised to certain points in the technic of management and operation. For example, the management of mammary complications is not in accord with the present state of our knowledge of the physiology of the breast and of the way to treat infections. The differentiation between engorgement and infection is not clearly made, and the statement that the temperature will usually be raised a degree or two while the milk is appearing is distinctly a mistake. The application of belladonna, hot fomentations and boric poultices in case a breast becomes hardened and inflamed will favor suppuration that could be avoided by the opposite line of treatment.

The statement that shaving the parts in serious operations is undesirable in private practice gives a doubtful impression of the general aseptic management.

The amount of space given to spinal anesthesia is astonishing; so is the statement that this method of anesthesia is suitable for forceps operation.

The reason for the continued employment of the side position in forceps operation is not understood by us. The results of the induction of premature labor in the six cases given were not very satisfactory, as four of the children were lost. Either the operation should be condemned or the cases should be criticized to show how the result can be improved. The extraperitoneal Cesarean section is not mentioned, while vaginal Cesarean section, with which the author has had no experience, is very briefly described.

The book is a successful attempt to present the conclusions of a teacher of much experience and illustrates the subject with frank unvarnished records of cases that reenforce the teaching and furnish a basis for the conclusions. Such a book cannot be other than a valuable addition to obstetric literature. The work is beautifully printed and illustrated.

Difficult Labor. A Guide to its Management for Students and Practitioners. By G. Ernest Herman, F.R.C.S., Consulting Obstetric Physician to the London Hospital. Cloth. Price, $2.50 net. Pp. 547, with 180 illustrations. New York: William Wood and Co., 1910.

This fifth edition of Herman's popular book on the management of difficult labor has been thoroughly revised and considerably enlarged, new illustrations having been added, together with a chapter on retroversion of the gravid uterus and puerperal eclampsia. The book is characterized by a clear dogmatic style, suitable for a manual designed for the practical use of students and practitioners. The heavy type headings of chapters and paragraphs and the clear arrangement of matter make the book easy to use in reference. It is evidently the work of an experienced teacher who knows what is needed by his readers.

In general the work is in accord with modern American obstetric practice. It would have been desirable, however, to add the metric measurements as many have learned these measurements instead of the English inches One is surprised to find little description of the aseptic technic of operation The use of gloves is not recommended, and the illustration of forceps operation shows bare hands and likewise no protection of the patient The operation is done on the bed with the patient in the side position Greasing the perineum is allowed, although the author doubts that it can help much in preventing lacerations

With these exceptions, the book is eminently practical The author has in mind the needs of the busy practitioner who will not remember too much of his theoretical training but needs clear and definite rules for action If these rules are not all in accord with the most modern trend of practice they represent at least the results of much experience and are perhaps as safe as the more radical methods of procedure that in some clinics have become popular in recent years The book is worthy of the careful study of all

Lehrbuch der Ohrenheilkunde Von Dr Victor Urbantschitsch O O Professor der Ohrenheilkunde an der Wiener Universitat und Vorstand der K K Universitatsklinik für Ohrenkranke Fifth Edition Paper Price 18 marks Pp 623 with 156 illustrations Vienna Urban & Schwarzenberg 1910

This is the fifth edition "completely revised and enlarged," of Urbantschitsch's comprehensive work The author takes up the anatomy and physiology of the organ to be discussed, following this with the clinical side of the subject There are many interesting illustrations throughout the book

In the study of the symptomatology and pathology of the various ear affections the author treats of a number of new matters in more detail than is found in most similar books Despite the fact that Bezold Politzer and others have long ago and repeatedly denied that hearing exercises can be of any value in cases of deafness Urbantschitsch still maintains his faith in them and describes his methods in detail

The Leidler and Schuler method of *x* ray examination of the mastoid is referred to and it would seem that skiagrams are of some assistance in the diagnosis of certain mastoid conditions The details of Bárány's modification of the Rinné test are given With reference to the physiology and pathology of the labyrinth, the author has drawn from and quoted the work done by Bárány and Ruttin Nystagmus is dealt with in detail. Bárány's work on the physiology and pathology of the semicircular canals (1907) is quoted, and one who has previously read but little regarding nystagmus can obtain a very good working knowledge of the condition Quite an interesting section is that dealing with the medicolegal status of injuries to the ear

All in all, the present edition is a very readable, clear, authoritative and valuable production

Insects and Disease A Popular Account of the Way in Which Insects May Spread or Cause Some of Our Common Diseases By Rennie W Doane A B, Assistant Professor of Entomology, Leland Stanford Junior University Cloth Price, $1 50 net Pp 221, with 112 illustrations New York Henry Holt & Co, 1910

This book gives, in untechnical language, an interesting account of the part insects play in the dissemination of disease The relation of house flies to typhoid, of mosquitoes to malaria, yellow fever and elephantiasis, of fleas to plague, of tsetse flies to sleeping sickness, and the suspected relation of insects to several other diseases are explained Some directions are given for destroying or expelling insect pests, and an excellent, though not exhaustive, classified critical bibliography, completes the book

A few typographical errors unfortunately tend to impair the reader's confidence in the carefulness of the proofreading and hence in the accuracy of the spellings used *Musca domestica,* for instance, on page 201 hides behind the alias of *Muca domestica,* M J Rosenau is referred to once as "Roseman" and twice as 'Rosenan," Finley and Ricketts are fellow sufferers

Apparently out of a laudable (but, we believe, mistaken) desire to spare the average reader, the legends for the illustrations which give magnified views contain no indication of the scale of enlargement In the case of the less familiar insects especially it would have been desirable to indicate the scale of magnification and perhaps to give a macroscopic picture by the side of the microscopic to aid in the recognition of the insect.

The Examination of the Function of the Intestines by Means of the Test Diet Its Application in Medical Practice and Its Diagnostic and Therapeutic Value By Dr Adolf Schmidt, Halle A S Authorized Translation from the Second Revised and Enlarged German Edition by Charles D Aaron M D Professor of Diseases of the Stomach and Intestines in the Detroit Post Graduate School of Medicine Price, $1 50 net Cloth Pp 126 with illustrations Philadelphia F A Davis Co, 1909

While not comparable with the examination of stomach contents, the examination of the feces after a test diet gives reasonable hope of greatly advancing our knowledge of functional disorders of the intestines The method of Schmidt has been somewhat simplified since the publication of the first edition, and may now be carried out by any practitioner with a minimum of technical skill and of laboratory equipment This method has stood the test of time, and is destined to outlive its competitors such as the desmoid test, the bead test, etc In the present edition Professor Schmidt has developed more fully the relations of the stomach, liver and pancreas to intestinal diseases and this chapter forms a valuable contribution to a neglected field of gastrointestinal pathology The last chapter, dealing with chronic constipation, presents the author's theory that in constipation digestion is too good and presents the reasons for the agar agar treatment which, unfortunately, has been appropriated by the proprietary interests The book is tastefully bound and well illustrated

Applied Anatomy The Construction of the Human Body Considered in Relation to Its Functions Diseases and Injuries By Gwilym G Davis M D, Associate Professor of Applied Anatomy, University of Pennsylvania Cloth Price $6 Pp 630 with 630 illustrations by E F Faber Philadelphia J B Lippincott Co, 1910

On account of the great mass of facts to be learned, the college course in anatomy is confined almost entirely to the descriptive work of the large anatomies Only meager and superficial attention is given to applied anatomy in the teaching of surgery and physical diagnosis With a fairly good grounding in descriptive anatomy, a year devoted to the study of applied anatomy would give a student an invaluable knowledge of the subject that would prove useful not only in his subsequent study of diagnosis and all the surgical branches, but would give him something that he could apply with immense advantage daily after entering on general practice This book with its numerous splendid illustrations of normal and pathologic anatomy and anatomic relations, and its practical text should prove of great usefulness, to student, general practitioner and surgeon in their daily work

VII Bericht der Deutschen Gesellschaft für Samariter und Rettungswesen fur die Jahre 1908 und 1909 Herausgegeben vom Vorstand Paper Pp 171 Leipzig Nikolaikirchhof

First aid and life saving institutions and societies scarcely have an independent existence in the United States, the combination of such societies into a national association originated in Germany The present volume is the seventh report of the German Association, which is now in the fifteenth year of its active existence It was formerly known as the Deutscher Samariter Bund but with the natural development and expansion of its work, two years ago took the present title The report includes, in addition to the ordinary proceedings of the society, reports on the progress of life saving work in various occupations and localities The articles are illustrated and afford useful hints to those interested in such work An extension of such associations is indicated as affording a preparation for emergencies in which life is liable to be sacrificed because the necessary men and materials for first aid are not at hand

The Diseases of Women A Handbook for Students and Practitioners By J Bland Sutton F R C S Eng, Surg on to the Middlesex Hospital and Arthur E Giles M D B Sc Lond F R C S Edin Suregon to the Chelsea Hospital for Women Cloth Price, $5 25 Pp 554 with 127 illustrations New York Rebman Company 1910

In the latest edition of this well known work on gynecology, the authors have *elaborated certain subjects such as fibrosis* and adenomyoma of the uterus and generally have brought the book up to date The pathologic classification of endometritis has been changed to correspond to the recognized nomenclature, and attention is called to the difficulties of differentiation between appendicitis and pelvic inflammation A description of the technic of Wertheim's operation for carcinoma of the uterus has also been added.

Medicolegal

Liability for Gauze Left in Abdomen in Gonorrheal Suppuration—Custom of Dressing Wounds and Keeping Track of Gauze—Expert Testimony

The Supreme Court of Iowa approves of a judgment in favor of the plaintiff in the malpractice case of Reynolds vs. Smith and another (127 N. W. R., 192). It says that an abdominal operation for the removal of a cyst or tumor was performed on the plaintiff January 16 by Dr. Schooler, a partner of Dr. Smith. Dr. Smith attended the patient until the 19th, when Dr. Schooler, who had been temporarily absent, resumed charge and attended the patient until her return to her home in Minnesota February 23. The wound had not entirely healed, and, on her arrival in Minnesota, a Dr. Schmitt dressed it. On the 27th he made an examination, and, according to his testimony, found a piece of surgeon's gauze about 16 inches square in the abdominal cavity and, after enlarging the opening, removed it. Though the wound then healed the plaintiff continued to be weak and suffered from melancholia for some time and in April of the following year, was operated on by Dr. Schmitt for hernia. This suit was brought to recover damages for that, as was alleged, the defendants were negligent in failing to discover and remove the gauze, subsequently extracted by Dr. Schmitt.

Counsel for the defendants contended that the record as a whole did not show that the defendants failed to exercise the degree of skill and care exacted in such cases. But that both were *eminent in their profession alone could not exonerate* them from the charge of negligence. The most proficient are subject to the *infirmities* of human nature, and, as the books demonstrate, sometimes may lapse below the standard by which their conduct is to be measured. The history of the patient was such as permitted of no relaxation in attention at and after the operation. At an operation five years before Dr. Schooler had removed her ovaries and Fallopian tubes, and at another operation had removed her womb. If she was afflicted with a gonorrheal affection, this may have exacted greater caution, or might have been thought to account for the delay in healing after the operation was performed.

Dr. Schooler testified that two gauze pads were left in the patient and Dr. Smith that he removed those pieces three days later. It was the habit of Dr. Schooler to knot the second piece of gauze inserted and Dr. Smith found one of those removed in that condition. He then inserted another piece of gauze several yards long to prevent bleeding and to act as a drain, leaving the end protruding through the wound. On Dr. Schooler's return on the second day thereafter he resumed charge and inserted a drainage tube and was of opinion that had there been gauze in the body he would have discovered it. Before the patient left for home he testified to having again examined her without discovering anything abnormal save the continued suppuration.

On the other hand, Mrs. Reynolds related that Dr. Smith removed some of the gauze on Thursday, after the operation had been performed on the Monday previous, cutting it off with scissors, and some more in the same way on the following day, and that she did not remember that any more had been inserted. Her husband's testimony was corroborative, and to the effect that Dr. Smith removed the last of the gauze on Sunday.

It will be noted that none of the witnesses pretended to account for the gauze inserted by Dr. Smith after removing the pads put in by Dr. Schooler, but it appeared to have been several times longer than that extracted by Dr. Smith. Of course neither of the defendants intentionally allowed any foreign substance to remain in the abdomen. No one so claimed. But the jury might have found that the gauze was taken therefrom as testified by Dr. Schmitt, that it should have been removed within a few days after the operation, that the failure of the wound to heal indicated an abnormal condition, and that, even though the patient had suffered from specific infection, this exacted careful examination as to the cause, and that all this being so, the issue as to whether had the defendants exercised that degree of skill and care required of them, the gauze would have been discovered and removed before the plaintiff left the hospital, was for the jury to determine.

The defendants requested several instructions to the effect that all exacted of them was that they follow the custom *and usages of physicians in the performing of such operations* in the vicinity where they practiced. These were rightly refused, for no evidence was adduced that any particular custom or usage in the matter of avoiding leaving the gauze in the plaintiff was actually followed. Moreover, if there had been such evidence, those instructions ought not to have been given, for, in view of the failure of the wound to heal, the continuance of suppuration, together with the significance of leaving such a substance in the body, the issue of negligence must have been submitted to the jury.

The evidence disclosed that nurses and the intern sometimes dressed the wound. They were not employees or agents of the defendants, and, unless the defendants were negligent in permitting this to be done by them, they were not responsible for their acts save in so far as their duty exacted examination of the wound and proper treatment. Had there been evidence tending to show that from the acts or omissions of the nurses and intern a gauze became lost and was allowed to remain in the plaintiff's abdomen the jury must have been instructed as above, but, in the absence of such evidence and especially in view of explicit instructions as to the necessity of an affirmative finding of negligence on the part of the defendants, there was no error in refusing to give an instruction of the character requested.

The intern was asked to explain the practice which obtained at the hospital in determining whether all gauze pads used in operations were accounted for. An objection to the inquiry was sustained. The ruling was correct, for there was no evidence that any precaution had been taken in operating on the plaintiff save by tying a knot in the second piece of gauze inserted. True Dr. Schooler testified that "we have a way or *method* by which to keep track of the various pieces put in there * * * The nurses count the pieces of gauze pads that are used." But the record did not indicate whether such way or method was followed in *performing the operation* on the plaintiff. Had there been evidence of how track of the gauze was actually kept, doubtless, as bearing on the issue of negligence, testimony that this was in accord with custom would have been competent. In the absence of such evidence, the rule is otherwise.

The jury were instructed, in part: "Though it is with a view of aiding you in determining the questions submitted to you that expert testimony has been admitted, you should bear in mind that the opinions of experts may be correct or incorrect, and that such testimony, depending on whether it tends to reveal the truth or otherwise, may or may not aid you in arriving at a correct conclusion, and that on you rests the responsibility of a true verdict. The expert testimony should be weighed and considered by you as you weigh and consider the other testimony, and taking into consideration the amount of skill and knowledge possessed by the witnesses giving expert testimony, the matters testified to by them, the other evidence and facts and circumstances of the case, you should give to expert testimony such weight and credit, and only such weight and credit, as you deem it justly entitled to receive. It is your duty to give to the evidence, and all of the evidence in this case, full and fair consideration and draw therefrom the conclusion which your judgment and consciences approve as just and right. When expert witnesses testify to matter of fact, from personal knowledge, their testimony, as to facts within their personal knowledge, should be considered the same as that of any other witnesses who testify from personal knowledge." The court does not think the instruction, when fairly construed, disparaged expert testimony or indicated that it might be rejected because such was its import. Like other testimony, it must reveal the truth in order to be of aid to the jury. That it may or may not be correct is also true. The manifest design of the instruction was to caution the jury against blindly accepting what experts on either side had said, as is often likely to be done, owing to the expert's knowledge and the jury's ignorance of the subject of inquiry, and to emphasize their duty to apply the same rules in weighing and testing expert as is applied to other testimony. The instruction is not open for fair criticism.

The jury allowed damages in the sum of $2,000, but the court thinks that excessive when it is considered that the operation was performed January 16 and that the gauze, which might properly have been allowed to remain for about a week, was removed February 27. The circumstance that the wound healed within a few days thereafter tended strongly to show that the consequences were not serious. That the patient recovered immediately after the operation for hernia in April of the following year tended to prove that the suffering from melancholia, headache, and insomnia were due to the hernia, rather than to other conditions produced by leaving the gauze pad in the abdomen. Dr. Schmitt thought the hernia due to the last-mentioned cause, but it was exceedingly doubtful as to the record warranting such inference. Wherefore, a remission of $800 from the judgment is made the condition for its affirmance.

AMERICAN ASSOCIATION FOR STUDY AND PREVENTION OF INFANT MORTALITY

First Annual Meeting, held in Baltimore, Nov. 9-11, 1910

The President, DR. J. H. MASON KNOX, JR., in the Chair

A summary of this meeting was given, with the election of officers, in THE JOURNAL, November 26, page 1903, and one of the reports was summarized and discussed December 3, page 1999.

The Duty of a Nation to Its Potential Citizens

DR. J. H. MASON KNOX, JR., Baltimore: One baby out of every five born dies before it is a year old. It is conservatively estimated that at least one-half of this infantile death rate is a toll paid to parental ignorance and indifference and can largely be averted. The best means of prevention is through an educational campaign, with the mother as the pivotal point. Among matters of fundamental importance are the prompt and accurate registration of births; maternal nursing, and the extension of the educational curricula in the high and normal schools to include better preparation for motherhood. This organization was formed as the result of a conference called by the American Academy of Medicine at Yale University, November, 1909. Permanent headquarters were opened in the Medical and Chirurgical Faculty Building, Baltimore, Jan. 1, 1910; 500 active members have been enrolled. Thirty-two states, the District of Columbia and Canada are represented. Thirty-three organizations, including nurses associations, milk dispensaries, child-helping societies, social settlements, health departments, etc., have become affiliated. The work of the year was devoted principally to educational propaganda. More than 8,000 pieces of mail were sent out from headquarters, and 22,000 circulars and leaflets were distributed. The headquarters have served also as a clearing house for information on matters pertaining to the reduction of infant mortality, and have brought many activities in various parts of the country in touch with each other.

M. JUSSERAND, the French Ambassador, described some of the preventive undertakings carried on in France, which have served as models for those in other lands, especially the Consultations for Nurslings established by Professor Budin. Twenty years ago, when the first of these was founded, a man of 90 had a better chance to live one week than a child one day old. Dr. Budin especially taught that thing which is so obvious, which like so many obvious things, had been lost sight of, for when a thing is obvious no one deems it worth while to think of and it soon becomes forgotten and has to be discovered again. The great discovery was that children are meant to be nursed by their mothers; that the best cow's milk cannot compare with the mother's milk. Nevertheless, there are cases in which recourse has to be had to cow's milk and mothers are taught what sort of sterilized milk they should employ. Along that line many children are saved. This invention is really a very simple one, but it has had such an effect that it is imitated throughout the country. Restaurants have been established at which food is provided free of cost to nursing mothers. Another feature of the French campaign against infant mortality is the teaching of hygiene in the elementary schools. An appropriate motto for the American Association for Study and Prevention of Infant Mortality is the three words: "Learn. Teach. Live."

PROF. IRVING FISHER, New Haven, Conn.: Evidences of the fact that interest in the problem of conserving our national vitality is greater to-day than ever before, are: the campaign against tuberculosis, the study of the pollution of streams, the campaign against the social evil, and finally the campaign directed toward the reduction of infant mortality. The latter has, perhaps, a wider popular appeal than any other. It is beginning, also, to appeal to the statesman and to some extent to the ordinary politician. Carefully gathered statistics which are published in the report to the government on national vitality, show that at least 125,000 of the 300,000 deaths among infants, which occur annually, could be prevented, if modern hygiene were universally practiced. No one who could realize the immense number of needless deaths, would need further argument as to the importance of this movement for the study and prevention of infant mortality. But the public, on the whole is apathetic and needs to be aroused. The assertion has been made in some quarters that effort directed toward the prevention of infant mortality interferes with the operation of the law of natural selection, that the results of such effort would be to prolong the lives of the weak, to increase the miseries of the poor and to reduce the average vitality of the next generation. A careful study of the situation shows that the argument is fallacious, that instead of interfering with natural selection the movement aims to remove the interferences with natural selection which modern civilization has created. It is not a feature of natural selection that babies' milk should be adulterated or contaminated with germs. The movement for the prevention of infant mortality amounts in the end simply to this—to give back to the baby what is the baby's natural birthright, namely, pure milk and pure air. The elimination of disease acts both directly and indirectly toward the improvement in health and vitality not only of the present but of the succeeding generations. Instead of going back to primitive conditions we ought to go forward. The cure for the evils of civilization is more civilization. In accordance with what seems to be biologic law, a lowered birth rate accompanied by a reduced death rate characterize the progress of animal organisms. Applied to mankind, the process makes for economy; the birth of a human being becomes a more important event; and it makes for the conservation of the life that is born. The conservation of infant lives is but part of the problem of the conservation of all human life. While more has been done by governments in other countries toward the conservation of national vitality than in our own land, the movement directed toward the establishment of a federal department of health has made steady progress. It has the endorsement of the President of the United States; of a number of far-sighted and patriotic congressmen, as well as of a large number of the medical and hygienic organizations of the United States. Opposition to the movement comes from special interests actuated by commercial motives. It remains for the people of the United States to say whether the commercial interests of those who produce the food for babies are to be put above the valuation of the babies themselves. And if the department of health, when established, shall have had the effect of restricting the freedom of those who would like to put into the stomachs of babies what is bad for the babies, it will have had for one of its results the reduction of infant mortality.

DR. ABRAHAM JACOBI, New York: The highest infant mortality occurs during the first few weeks of life; inheritance is a powerful factor in the formation and the health of the baby; the diseases and frailties of the parents will be reproduced, actually or potentially, in the offspring Parents with hysteria or epilepsy or other nervous diseases with diabetes, alcoholism, criminal instincts or other forms of insanity, insure dispositions to kindred, if not the same affections Syphilis is fatal to the embryo or fetus, dangerous to the baby, who frequently succumbs to its ravages within a few days or weeks Tuberculosis in the mother will only predispose the baby, open tuberculosis will directly infect the nursling—it may be, the first day or week So individual caution of the present generation will or may and must, safeguard the existence of the child that is to be Marriages are not permitted between the immature even now, they should be prohibited among the advanced tuberculous, the insane, the incurable epileptic the hopeless criminal

Our young doctors, unless they have had the great luck of being taught in obstetric wards and practice, learn, if at all, at the expense of the women who bear children and of the infants that are borne by them Our medical schools do not begin to convey adequate obstetric knowledge and practice to the students The number of poor who suffer for want of the safety vouchsafed by knowledge and by means, increases every year Only a part of the deaths due to puerperal fever are attributed to it other causes such as acute Bright's disease, peritonitis pneumonia being inscribed on the death certificates Puerperal fever is avoidable, its occurrence is a scandal and a shame in the community—like small pox or typhoid fever, and no actual precaution is taken to avoid it Poor agricultural Prussia had its well informed and trained and supervised midwives a century ago There was and is no village in that country without one We, however, have none that compare with them We cling to our prejudices and our indolence Forty years ago the midwife question was discussed in a large New York medical society One per cent of the members present voted for instructing, and licensing and supervising them And this very day the system under which they practice is slovenly and shiftless, no instruction is held out, no examination is held and the infant mortality of all classes, which you are bound to combat, is increased

Dr William H Welch, Baltimore I believe this movement initiates one of the most important campaigns in preventive medicine in this country In spite of the triteness of statistics it is enough to arrest one's attention when one learns that in the state of Maryland over one fifth of all the deaths of all ages occur under one year of age, that one third of all the deaths occur under five years of age, the negro death rate making the percentage higher than in some other places In the registration area of the country, the deaths under one year of age are a little less than one fifth of all deaths of all ages, and about one third under five years of age One ninth of all the deaths occur in the first three months of life The crusade directed toward the prevention of infant mortality will yield the quickest results if waged against the so called diarrheal and intestinal disorders, the acute respiratory diseases bronchitis and pneumonia and the infections Nurslings are better protected against infections than children who are artificially fed

One of the most important functions of the association is the enlightenment of the public Such education of the public is required to secure the enactment of the necessary laws from the legislatures and the appropriation of the funds needed to carry out preventive measures Another function should be to stimulate better sanitary organization and administration throughout the country With this end in view it should lend its whole force toward the organization of a national department of health and should stand for a strengthening of the activities of the federal government in public health work A bureau of child hygiene would be an essential feature of such a federal department of health A campaign in the interest of the better registration of births, the correlation of existing agencies now acting separately for the reduction of infant mortality, the stimulation of investigation, the formulation of a definite program of prevention, are also among the functions of the association The direct benefits to be derived from the application of such measures would of course justify all efforts The indirect benefits would be equally great

(To be continued)

TRI STATE MEDICAL ASSOCIATION OF MISSISSIPPI, ARKANSAS AND TENNESSEE

Twenty Seventh Annual Meeting, held at Memphis, Tenn, Nov 15-17, 1910

(Concluded from page 2068)

Diagnosis and Treatment of Kidney Calculi

Dr W S Anderson, Memphis The Roentgen ray as a means of diagnosis marks the most important advance made in kidney and ureteral stone surgery in *modern times* The clinical picture of a renal calculus often resembles very closely that observed in other pelvic and abdominal troubles. A careful study of the urine is of the greatest importance in cases of suspected stones Among some of the commoner conditions liable to be mistaken for stones are (1) tumors and tuberculosis of the kidney, ureter and bladder, (2) acute or chronic appendicitis, (3) movable or floating kidney, with kinking of the ureter, (4) pain on the right side caused by biliary and pancreatic calculi and intestinal obstruction; (5) psoas or perinephritic abscess

If the kidney is found much diseased it is best to remove it at the time of the first operation rather than to attempt it later for this is usually a difficult as well as a dangerous operation on account of many adhesions

DISCUSSION

Dr E M Holder Memphis By means of the Roentgen ray with modern focusing devices one is able to get a clean-cut, clear, precise, well defined picture of stone in the kidney or bladder It is easier to take an *x* ray of the kidney than of the bladder, for the reason that it is not surrounded by a bony wall

Dr Frank D Smythe, Memphis· One condition has prevented me from making a correct diagnosis of stone in the kidney, and that is acute torsion of the pedicle of an ovarian cyst A physician treated a case for days and regarded it as one of stone in the kidney Examination of the urine revealed a stone in the kidney or ureter, and I was called to perform the operation I regarded it as a case of peritonitis due to rupture of some organ producing infection and advised immediate operation On making an opening I found an ovarian cyst as large as a fetal head, with two or two and a half twists in the pedicle, with rupture of the blood vessels, the cyst undergoing gangrene.

Pistol-Shot Wound Through the Head

Dr Joseph T Seymour, Whiteville, Tenn. The patient was a boy, 15 years of age, who accidentally shot himself through the head while examining a pistol The ball entered the head on the right side near the external angular process of the frontal bone, just above the supra orbital ridge passing through the skull and brain on a straight line making its exit at the junction of the parietal, occipital and mastoid portions of the temporal bone The opening at the point of exit was about the size of a nickel, being much larger than that at the point of entrance Free drainage was established and the patient made a good recovery

DISCUSSION

Dr J W Barksdale, Winona, Miss Six or seven years ago, a man was shot with a 44 caliber Smith and Wesson pistol The bullet passed through the right eye and through the entire thickness of the frontal lobe of the brain, emerging just anterior to the outer central fissure I saw the man three minutes after the reception of the injury There was no loss of consciousness, no paralysis, there was never any symptom suggestive of brain injury during the entire time, other than the physical fact of the injury After recovery, which was uneventful, the patient had several convulsive seizures in the succeeding two or three years, dying four years later of tuberculosis

Dr J R Nelson, Whiteville, Tenn· One singular feature in connection with the case reported by Dr Seymour is that the boy was rational all the time

Dr John Darrington, Yazoo City Miss It is the general practitioner who is called on to treat cases similar to the one reported. Dr. Seymour's patient would have recovered without any complication whatever, except that the external opening was not sufficiently large in the first place to allow free drainage, but had to be enlarged later. It is remarkable how much traumatism the brain can stand. I saw a case in which the skull was crushed over an area an inch and a half in diameter, with pressure on the brain. The pressure was relieved, and the man recovered.

Dr. J. N. Murray, Ripley, Miss.: A negro was kicked on the side of the head by a mule. Two or three tablespoonfuls of brain substance escaped. The boy had had epileptic convulsions previous to the injury. I trephined, removing a spicule of bone from the inner table an inch and a half long. The boy recovered from the operation and has not had an epileptic convulsion since.

Benign Tumors of the Uterus

Dr. E. M. Holder, Memphis: It is conservatively estimated that over two-thirds of women having fibroid tumors of the uterus will die if not subjected to operation. The mortality of myomectomy and hysterectomy is between 2 and 10 per cent., depending on the gravity of the case, on the operator, and on the environment in which the operation is done. It seems a fair conclusion that the resort to early operation will effect a saving of 25 to 30 per cent. in mortality. The rule of practice should be to remove all fibroids which come under observation, unless there seems to be some good reason for temporizing, due either to the small size of the tumor, or to the advanced age or poor general health of the patient. Whenever the disease causes displacement, hemorrhage, pain or pressure sufficient to threaten damage to the general health, to the nervous system, or to the pelvic organs, an operation should be advised. When pregnancy is found to be complicated by a fibroid tumor, it is best to allow pregnancy to go to term as long as the mother's health is not seriously in danger. If, at the onset of labor, or shortly before, it seems certain that the tumor will cause obstruction to the birth of the child, Cesarean section, possibly followed by hysterectomy, should be performed. In cases in which the death of the child makes it necessary to interfere in the earlier months, abdominal section should be performed and an attempt made to enucleate the tumor. If under these circumstances myomectomy is found to be dangerous, hysterectomy should be performed.

DISCUSSION

Dr. William Krauss, Memphis: The terms "benign" and "malignant" are entirely clinical conceptions. They do not carry with them any distinct line of demarcation with reference to the histology or histogenesis of the neoplasm. Sometimes it is extremely difficult for the laboratory man to decide whether a given histologic structure is compatible with a benign clinical course, or whether it is going to mean that the course will be seriously malignant. What are the data for clinical malignancy? The tumor must show evidences of a tendency to spread into the surrounding tissues. There must be a tendency to local recurrence. There must be a tendency to metastasis. It must produce cachexia. These tumors are said to undergo sarcomatous or carcinomatous degeneration. The pathologist knows of no such degeneration. A fibroid tumor being mesoblastic, it can only undergo metablastic changes. It is not a degeneration.

Dr. Frank D. Smythe, Memphis: As the result of my observation and study of hundreds of cases of fibroid tumor I cannot regard a fibroid tumor or myoma of the uterus as a simple tumor. The location of a fibroid tumor rather than the size is the one thing that demands immediate operation. These tumors are of slow growth, but they grow steadily, and in the long-standing cases they are likely to produce serious remote disturbances. There should be little or no mortality attending the operation for the removal of fibroid tumors in the hands of good surgeons. The unavoidable deaths which occur in those cases following operation are always in patients who have had these tumors for a long time, whether they be large or not. Our object is to do the best we can for the patient, and from my own experience I believe the interests of the patient are best served in the main by hysterectomy, and hystero-salpingo-oöphorectomy when the tubes and ovaries are implicated, and these organs are implicated in 50 per cent. of the cases.

Dr. W. T. Black, Memphis: In a woman approaching the menopause hysterectomy should be done in the class of cases under discussion because in 4 per cent. of the cases these tumors undergo malignancy. In a woman already pregnant myomectomy is indicated.

Prevention of Infantile Diarrhea

Dr. A. G. Jacobs, Memphis: The prevention of diarrhea in babies depends on three factors: 1. Proper care should be taken of mother's milk. 2. If this fails, a wet-nurse should be procured. 3. If human milk cannot be secured, properly modified, pure uncontaminated cow's milk should be given. If this method of proceeding is followed, the death-rate from infantile diarrhea will dwindle down to one-fifth of its present proportions.

DISCUSSION

Dr. William Krauss, Memphis: If we are informed as to the methods of keeping the mother up to standard and supplying the infant, the problem is solved without going any further. It is not only a question of getting pure cow's milk as a substitute. The recognition of the proper proportion of the approximate principles in the milk is only one part of the problem. One-half of the protein of mothers' milk is in the form of a soluble albumin. The cow's protein is nearly all casein. This soluble albumin further has the advantage of having been prepared by the mother for emergencies further than the mere preservation of nutrition. Commercial milk, the best that is obtainable, produced in as clean a way as possible, and delivered within three hours, after being obtained under the most favorable circumstances, will contain probably fifty thousand bacteria per cubic centimeter. Grocery milk contains about ten times as many bacteria, and that is what we feed babies. Unless provision can be made whereby milk is delivered at the house containing a minimum number of bacteria, we are bound to have a high mortality among infants in the summer months, aside from the failure to protect the infant against the accidents which may occur in the household from disease and against which it would be protected by the normal protective bodies present in the mother's milk.

Treatment of Acute Middle-Ear Suppuration

Dr. W. L. Simpson, Memphis: Early free antiseptic opening of the drum is to be recommended in acute middle-ear suppuration. If adenoids are present, do not wait until the suppuration has become chronic, hearing bad, etc., before their removal, but operate as soon as diagnosticated. The mastoid operation in acute middle-ear suppuration is not to be a life-saving procedure, but should be done early to save hearing, prevent chronic suppuration, brain or labyrinthine complications, etc.

DISCUSSION

Dr. Eugene Rosamond, Memphis: I would like to emphasize the importance of the general practitioner being equipped so as to be able to do paracentesis of the drum membrane in acute suppuration of the middle-ear. There is no excuse for a doctor not having a head-mirror, with a set of speculums. With an ordinary electric light, even with the bright light of a window in the daytime, with a good head-mirror, there is no trouble in seeing the ear-drum, if we are patient and careful enough and take time enough to cleanse the canal.

Dr. W. S. Anderson, Memphis: I wish to emphasize the advantage of paracentesis of the drum membrane in cases of acute suppuration of the middle ear.

Dr. B. L. Branch, Collierville, Tenn.: I use an ordinary pipette instead of an ear syringe, for the purpose of cleansing the ear, as one can control the force which is used in throwing the water into the ear to greater advantage than with the ordinary ear syringe, and it does not cause any pain.

Buboes and Their Treatment

Dr. George R. Livermore, Memphis: I prefer the Hayden operation for the relief of buboes. A man had had several incisions made on either side, was confined to bed for months with suppurating inguinal adenitis, and yet following the Hayden operation he was able to be up in a week or ten days, the result being very gratifying.

DISCUSSION

Dr. William Krauss, Memphis: A patient with bubo had been under the care of a number of specialists without relief. The patient had induration and softening of the skin over the bubo with a little reddening, and from time to time it became very painful. I thought it would be a good case for vaccine treatment. The patient received five injections of the combined vaccines, and he is now entirely well. It took this man just two weeks to get over a condition that had lasted for eight years.

Plaster of Paris as a Primary Dressing for Fractures

Dr. J. W. Barksdale, Winona, Miss.: In using plaster as a primary dressing, a strip of ordinary bandage should be laid lengthwise along the limb, preferably along the front, between the padding and the plaster. Before hardening is complete, the plaster should be cut completely through over its entire length, this being rendered easy of accomplishment by cutting down on the roller bandage, which is pulled up into the cut plaster, thereby facilitating the maneuver. After being cut the roller bandage should be run firmly around the limb so as to keep the plaster snug and prevent splitting. The ends of the fingers and toes should be left exposed so as to permit of frequent inspection and should the swelling create discomfort, or threaten gangrene, the roller is to be taken off and the plaster sprung so as to accommodate the increased bulk. As the swelling subsides the bandage can be drawn as tightly as desired, so that the enveloping material at all times keeps up an even pressure and secures coaptation. If the use of this material as a primary dressing has a drawback, I have thus far failed to discover it.

DISCUSSION

Dr. John L. Jelks, Memphis: When I put a plaster of Paris bandage as a primary dressing on a limb that has been fractured, I am very anxious about that case after the first day or until I cut the bandage and inspect the limb. Plaster of Paris can be adjusted to the contour of the limb better than any other splint we employ.

Dr. Battle Malone, Memphis: The best results I have obtained is in cases in which the plaster splint has been put on at the earliest possible time after the accident. I do not agree to the use of plaster of Paris in fractures of the upper extremity. In fractures about the elbow joint it is essential that we should have a dressing that can be removed, and the dressing should be put on in such a way that we can use passive motion, beginning it early, and keeping it up every day with massage.

Treatment of Failing Compensation in Cardiovascular Disease

Dr. Bryce W. Fontaine, Memphis: To relieve the distressing symptoms we must decrease the work of the heart and increase its strength and restore to proper working order its functions. There is no single measure so important in the treatment of some patients as a temporary venesection. The presence of hydrothorax must never be overlooked. Paracentesis in this condition will give immediate relief. The specific effect of digitalis in the stimulation and restoration of tone to the heart muscle has yet to be approached by any other drug. Its action is remarkable in that it stimulates specifically several different functions of the heart muscle. It is indicated in every case of failing compensation, except, perhaps, a few cases of extreme mitral stenosis, and in cases of marked arteriosclerosis. It should be given in doses of one grain, every two hours, until its physiologic effect is noted, then discontinued and resumed in five to seven days, if dyspnea and edema are not diminished. In cases due to arteriosclerosis, and accompanied with high blood pressure, vasodilators are necessary, and are often very efficiently used in conjunction with heart stimulants. Carefully regulated exercises and carbonated baths aid in the peripheral circulation and markedly increase the tone of the heart muscle. In our efforts to reduce the anasarca and to relieve dyspnea, we must not forget the beneficial effect of restful sleep.

DISCUSSION

Dr. Frank A. Jones, Memphis: With reference to the treatment of renal, cardiac, or cardiorenal lesions, the time has come when we are not so prone to administer too large quantities of digitalis and the large doses of salines as we formerly were, but I have come to realize in my individual work that we have no better agent than the Nauheim baths. The Nauheim bath can be improvised in any home where there is a bath tub. As to the use of digitalis, there is but one valve lesion on which it has any marked effect, and that is mitral insufficiency, when failing compensation takes place.

A Form of Primary Nasal Diphtheria

Dr. E. C. Ellett, Memphis: In twelve years I have seen about two cases a year. The cases have all occurred in children, from 4 to 10 years of age. The children were not apparently sick, and were thought to be suffering from a cold. There is no elevation of temperature, no glandular involvement. Nosebleed is frequent from detachment of the membrane by blowing and picking, and excoriations of the upper lip and nostril are the rule. Inspection of the nostril shows a membrane, adherent to the septum most often and completely stopping the nose. At times the attempt to dislodge this will cause bleeding. It looks like a plug of muco-pus, but can be made out to be a membrane attached to the mucous membrane of the nose. Culture shows the characteristic bacilli. The treatment by antitoxin, even at the end of two or three weeks, is very effective. All my patients have recovered and in no case has any postdiphtheritic paralysis occurred. If antitoxin is given at once in suspicious cases the patient is well before the culture can be made, and I think that we should follow this plan and not wait.

DISCUSSION

Dr. Richmond McKinney, Memphis: I should like to emphasize the fact that this disease is mildly contagious. I have seen two or three of these cases a year. In no case did the disease extend to the fauces. One patient with a malignant type was cured in forty-eight hours after the use of antitoxin. In this case we obtained pure cultures of the Klebs-Loeffler bacillus.

Dr. William Krauss, Memphis: Because the little patient is not very ill the condition is overlooked, but as soon as the organisms are transplanted into another soil, they may give rise to more virulent diphtheria and an outbreak in the family.

Dr. W. L. Simpson, Memphis: The cases of diphtheria of the nose I have seen have tallied with the description given. The patient's nose is stopped up either on one side or both, and there is usually some bleeding from the nose although the child is up and around the house and able to play. I think smaller doses of antitoxin than those usually given in the ordinary case of diphtheria of the throat would be followed by equally as good results as the larger doses.

Dr. W. F. Clary, Memphis: The first case of purely nasal diphtheria I ever saw was about four years ago. I investigated that case very carefully and had cultures made immediately, which showed the Klebs-Loeffler bacillus, and the use of antitoxin cleared up the case in twenty-four or forty-eight hours. In this case I noticed a free, ichorous discharge and excoriation of the upper lip. Since then I have seen about one case a year.

The following papers were also read: "The Trials and Tribulations of Skin-Grafting," Dr. R. F. Mason, Memphis; "Gall-Stones with the Complication of Pancreatitis," Dr. W. F. Clary, Memphis; "Report of a Case of Typhoid Fever with Cholecystitis and Cholangeitis," Dr. John O. Gurney, Tupelo, Miss.; "Treatment of Typhoid," Dr. M. S. Pollard, Thornton, Miss.; "Was Hysterectomy Indicated?" Drs. W. D. Ray and S. A. Brevard, Memphis; "A Case Having Symptoms of Abscess of the Temporal Lobe of the Brain," Dr. J. R. Nelson, Whiteville, Tenn.; "The Doctor's Privilege and His Justification," Dr. W. L. Howard, Greenville, Miss.; "Aneurisms of Abdominal Aorta," Dr. W. T. Price, Memphis.

COLLEGE OF PHYSICIANS OF PHILADELPHIA

Regular Meeting, Held Nov. 2, 1910

The President, Dr. George E. de Schweinitz, in the Chair

Nervous Disturbances Following Surgical Operations and Anesthesias

Dr. S. Weir Mitchell: In a case of grave hysteria following operation we must consider the patient as a loaded gun, and that the surgeon merely pulls the trigger. The proper man might know that the gun is loaded. This raises the question whether it is not desirable in many cases to prepare the patient for the operation more often than our surgical brothers seem to think is needed. Not only the risks of death are to be considered but the possibility of increasing a preceding condition of disease. Many physicians have felt that there is necessity for more strictly dealing with the before and after of surgical cases. Sir James Paget never did a grave operation on the bladder without putting the patient under a fort night of milk treatment. I am tempted to say that no operation ought to be done without obedience to the rule in St. Bartholomew's Hospital in London, that no surgeon should ever dare to operate on a patient except after consultation with two physicians.

Postoperative Psychoses

Dr. James G. Mumford, Boston: The frequency of postoperative psychoses is shown by the careful study of cases seven and nine years after operation taken from consecutive reports in hospital records. Long-continued mental and psychic disturbances following operations are due to demonstrable microscopic changes in certain nerve cells of the brain.

The Diagnosis of the Postoperative Psychoses

Dr. J. Chalmers DaCosta: All sorts of mental disturbances may follow a surgical operation. It is certain that genuine insanity may arise after an operation, though it is rare. Postoperative insanity is more common in women than in men and less common in children than in adults. Contributory causes are pain, insomnia and shock. In all cases of postoperative insanity there is predisposition, hereditary or acquired. A normal, stable brain will probably never go insane after operation unless that operation attack the brain, testicles, or ovaries. The anesthetic is usually the exciting cause in insanity coming on immediately after the operation. The commonest type of postoperative insanity is confusional insanity. Fear and worry are two important causal factors. Anteoperation fear may become a postoperative phobia, yet, I do not believe that fear or sudden fright is usually responsible for postoperative insanity. Most people go to the operating room with reasonable calmness, many with heroic courage, and some with satisfaction at the prospect. Delirium may be mistaken for insanity, and is far more common, from intoxication or infection, than organic brain disease. The entire subject of postoperative psychoses is one of extreme interest and importance.

Postoperative Insanities

Dr. Edward N. Brush, Towson, Md.: It may be assumed that there is no such thing as postoperative insanity *per se*. Insanity follows operations sometimes but it manifests itself in various forms. The personal and family history in a given case are so difficult to obtain that we are not at all sure how far mental instability plays a part. This naturally arises from the lack of clinical experience in psychiatry on the part of many observers of these cases. Quite a large proportion of postoperative insanities are due to sepsis not necessarily from faulty technic on the part of the surgeon. I have knowledge of a woman of unstable mental equilibrium who became insane after the administration of gas for the extraction of teeth and who remained insane for several months. Before we can study intelligently postoperative mental disturbances we must have the histories of our patients carefully recorded. From the lack of this knowledge the postoperative insanity is often erroneously attributed to the operation when in reality the condition may have been present preceding operation.

DISCUSSION

Dr. Howard A. Kelly, Baltimore: Postoperative psychoses I believe are due to the mental shock of the operation *per se* and not necessarily to any particular kind of operation. The duration and severity of the procedure are minor factors. The condition is due rather to the attitude of intense expectancy, even of dread, inspired by a new and untried force with which the patient feels she has to cope. It is important that the physician should be able to inspire the patient with confidence sufficiently to enable her to feel that he is a moral support. The conditions after operation should be as natural as possible and the patient should be out in the sunlight upon the porch when practicable. Treatment should be prophylactic in determining the predisposing factors. The utmost care should be taken to minimize the unpleasantness of the operation.

Dr. Edward Martin: I think every surgeon feels that when Dr. Mitchell said "the surgeon pulled the trigger" he practically covered the whole subject. We do not recognize that a perfectly healthy individual in good mental health can be made insane by any form of surgical intervention practiced at the present day. We do recognize certain postoperative mental disturbances as rather common. We see the type of depression which we call "hospitalism" of which the patient is cured by being sent out of the hospital. We see the type of homesickness and again the patient is cured by being sent home. We do not see the type in which the patient is depressed by the thought of loss of organs, and broods on a physical deformity.

Dr. Francis X. Dercum: The great rôle played by neuropathy in postoperative mental disturbances should discourage operation in such subjects, except under circumstances of grave necessity.

Dr. John K. Mitchell: Of 344 cases of general mental or nervous disturbances there were only thirty-one cases which could be called postoperative. There seemed to be no relation between the severity of the operation and the severity of the mental disturbance. Fright, I feel sure, plays a larger part than is generally attributed to it. There are good surgical reasons for getting a patient out of bed as soon as possible, but these troubles would be less frequent if the period of rest in bed were increased and general treatment instituted. Should the question of surgical treatment of a neurasthenic patient arise, much more than ordinary care must be observed in deciding on operation.

Dr. Charles K. Mills: Of many serious cranial operations under my observation I can recall perhaps only two or three in which insanity has followed the procedure. There have been very few also following operations on the spinal cord. In my experience these insanities have occurred in women of a certain temperament and of a certain predisposition rather than in the neurasthenic type.

Dr. S. Weir Mitchell: The question arises concerning the result of the use of local anesthesia which has become so fashionable in some circles. I hear of abdominal operations done under local anesthesia. I think to have the interior of one's abdomen exposed to one's own view would tend as much as possible to produce some of the insanities of which we have been speaking. It is a fact that occasionally insanities have been cured by grave operations. One such case was an amputation. Another was an attempt on a man's part to cut his throat. The man bled almost to the point of death, but his life was saved, and he recovered from his insanity. I do not recommend the method. I have seen many cases in which sudden delirium or sudden delusion followed instantly on a gunshot wound. One case was that of a colonel who, after being shot, cried to his men to run, that the rebels were on them. He fell on his face, was delirious for some time, but after amputation of his arm, he returned to the regiment that evening. Another case was that of an officer in the Mexican War, a man of well known courage. A ball struck his heel, he limped up and down the line calling to his men to run that everybody was going to die, and for hours he was in a condition of the wildest maniacal excitement. This passed away within forty-eight hours. He asked for a court of inquiry which, of course, was denied a man so well known for courage.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

November 24

1 Technic of Operations for Stone in the Ureter. H. Cabot, Boston.
2 *Staining Capsulated Bacteria in Body Fluids. W. H. Smith, Boston.
3 Cancer of the Scrotum. R. M. Green, Boston.
4 Technic of Arthrotomy. C. F. Painter and A. P. Cornwall, Boston.

2. **Staining Capsulated Bacteria.**—The following method of staining capsulated bacteria in body fluids has been found during the past two years, in Smith's hands, to yield more uniform results than any other:

1. Make a thin smear from fresh sputum, lung, pleural or pericardial exudate.
2. Pass through flame.
3. Cover with 10 per cent. aqueous solution of phosphomolybdic acid.
4. Wash in water.

If the microorganism is Gram-staining like the pneumococcus or *streptococcus mucosus capsulatus,* stain with:

5. Aniline oil gentian violet, steaming one-quarter to one-half minute.
6. Wash in water.
7. Treat with Gram's solution of iodin, steam one-quarter to one-half minute.
8 Decolorize with 95 per cent. alcohol.
9. Wash in water.
10. Stain with 6 per cent. aqueous solution of eosin (Grübler's w. g.) one-half to one minute, warming gently.
11. Wash in water.
12. Wash in absolute alcohol.
13. Clear in xylol and mount in Canada balsam. The capsule will be found to be distinct, clear cut, eosin-stained, about the Gram-stained microorganism.

If the microorganism is Gram-decolorizing, after covering the smear with phosphomolybdic acid and washing,

1. Stain with 6 per cent. aqueous solution of eosin from one-half to one minute, warming gently.
2. Wash in water
3. Counter stain with Loeffler's methylene blue from one-quarter to one-half minute, warming gently.
4. Wash in absolute alcohol.
5. Clear in xylol and mount in Canada balsam.

The capsule will appear eosin-stained about the blue-stained microorganism.

9 *Preliminary Examination of Children at Dispensary as Means of Protection Against Contagious Diseases. S. Welt-Kakels, New York.
10 Practical Value of Positive Complement-Fixation Test in Syphilis. G. W. Vandegrift, New York.

9. **Examination of Children at the Dispensary.**—Kakels describes the method of preliminary examination of patients at the Mount Sinai Hospital which has been in use for two and a half years past. This is the first dispensary in the city which has initiated such a system, and the number of its patients is very large, indeed. As the patients pass in they go between rails and are sent by the orderly to a physician who examines the throat and skin of each child. If a contagious disease is detected the child is taken to an isolation room. Non-contagious diseases that need immediate treatment may also be detected. There is at present in all dispensaries a great lack of care in handling contagious diseases, and as at present conducted they aid in disseminating them. The dangers would be much lessened by a preliminary examination of all attending children, and as a sanitary safeguard it should be established in all institutions. Kakels concludes by stating:

1. There is at the present time an evident lack of prophylaxis in handling contagious cases at the dispensary.
2. As at present conducted, dispensaries contribute to the dissemination of infectious diseases among the poor by contact infection in the common waiting-room.
3. If not entirely eliminated, the danger of exposure is lessened by the preliminary inspection of children, a prophylactic measure which aims at an early detection and exclusion of contagious cases and "suspects" before entering the common waiting-room.
4. Preliminary examination of children has been conducted at the Mount Sinai Dispensary since April, 1907, with satisfactory results.
5. Its establishment in similar institutions is required as a sanitary safeguard and on the ground of public economy.

14. **Introduction of Gas Into Blood.**—According to the general experience of investigators on this subject, a dose (from 60 to 100 c.c.) of air given at one time, constitutes the usual fatal dose, causing death almost instantly. Ninety-five cubic centimeters intrajugularly in Fitzpatrick's and Atkinson's experiments in untreated normal dogs always caused death instantly. After a number of experiments with the previous introduction of glycerin or olive oil into the femoral vein, to prevent foaming or churning after introduction of large quantities of air, they have found that the use of these substances is not necessary and they have obtained as good results without the use of olive oil or glycerin. The intravenous administration of 3.5 c.c. of a 50 per cent. solution of glycerin in normal salt solution in a 35-pound dog was followed by the rapid introduction of 28 c.c. of air (femoral) without any harmful symptoms or any trace of a kymographic disturbance. The next experiment, the dog weighing 10 pounds, was made to determine the toxic dose of glycerin when injected intravenously. The introduction of 7 c.c. of a 50 per cent. solution of glycerin in normal salt solution caused an immediate and marked drop followed by a slight rise in the arterial pressure. This was followed by another equally short drop in pressure, with heart paralysis. Respiration continued for a time and quite suddenly ceased. They believed at first that these experiments would be explained by supposing that an increased viscosity of the blood was acquired through the introduction of glycerin and olive oil, that these substances gave an increased tolerance for the presence of air in the blood-stream or that the oil acted on the blood mixed with air as oil on the breaking waves of the stormy sea, in that it prevented the bubbles or waves from breaking, and thus gave the heart a solid medium to compress on. But the experiments on the untreated dogs show these previous injections of glycerin or oil to be unnecessary. It would, moreover, appear to be probable that small amounts of air are absorbed in the blood-stream before it reaches the heart. The authors believe that they have found evidence that the adrenals play a very important rôle in enabling the lungs and the circulatory apparatus to eliminate the air introduced. It is apparent, moreover, that if the air is eliminated by this means it is possible that it is carried in by the same means.

34. **Valvular Heart Disease.**—This was an ordinary case of double mitral disease of many years' duration, in an individual who subsequently became insane, with numerous attacks of broken compensation, but there are a number of interesting facts connected with the case. First, it was rather curious to note the way in which insanity returned and became progressively worse hand in hand with a most remarkable improvement of the patient's cardiac action and general physical condition. Secondly, the pulse tracings demonstrate graphically the manner in which digitalis slows the pulse and increases the pulse volume, and how it changes the hopeless irregular pulse of a nodal rhythm into an orderly, regular, and continuous bigeminus form; and how, when it is pushed still further, it causes the second beat of each bigeminus to drop out in the peripheral arteries entirely, thus producing a false bradycardia. When, however, the drug is continued beyond this point its effects are not so good. A tracing taken five days after digitalis had been withdrawn, shows the persistent effect of the drug in the latter two-thirds of the tracing, in which the heart has suddenly and without apparent cause changed to the bigeminal rhythm. This is also shown in a later tracing in which a bigeminus which was still present six days after the withdrawal of digitalis suddenly disappeared during a period of voluntary apnea. The effect of digitalis in increasing tonicity—diminishing dilatation—is shown in a tracing in which the hitherto systolic retraction of the apex beat is changed into a systolic elevation. This change went hand in hand with a marked amelioration in the patient's condition. The action of the digitalis in producing bigeminus is not an accidental one. It occurred in the present case on each occasion when this drug was administered in sufficiently long and large dosage; and disappeared each time that digitalis was withdrawn long enough to allow its physiologic effect to pass off.

35. **Adolescent Hallux Valgus.**—In the preparation of this paper 134 fresh skeletons of feet were examined by Young, to determine the relative frequency of this affection, as well as its etiology. The condition was found to exist in seven feet, and in these was found a peculiar change in the articular surfaces of the first tarso-metatarsal joint, which appears to be characteristic, and in some degree causative. It was also noted that there is often present in the first tarso-metatarsal joint in subjects afflicted with this deformity, a wedge-shaped supernumerary bone similar to, or related to, the inter-metatarseum described by Dwight. Young proposes an operation for its relief. The foot having been carefully prepared and rendered aseptic, a curvilinear incision, 3 inches long from the instep, the center of which is over the first metatarsal phalangeal articulation; the flexor hallucis tendon is retracted to the inner side, the joint is exposed by a Farrabouf periosteotome, and the triangular piece of bone is removed by means of a chisel. As there is one difficulty in recognizing the articulation, this is best accomplished by using a steel meter measure or a wooden tongue compressor which has been marked from the *x*-rays, the distance being taken from the distal end of the first metatarsal bone to the joint. The removal of this triangular piece of bone leaves a space, which is corrected by placing the foot in a marked equinovarus position. A triangular piece of gauze is placed between the first and second toes and a pad is placed beneath the arch of the foot and a small straight wooden splint is placed along the inner side of the foot over the metatarsal phalangeal joint. The foot is secured in this position in plaster-of-Paris dressing and maintained for three months. In adults, the writer recommends the Wilson, Riverden, or Riedl's operation, according to the severity of the cases.

48 *Malaria in Early Infancy. F. Beekel, Cleveland.

44. Also published in the *Bulletin of the Johns Hopkins Hospital*, November, 1910.

45. **Diphtheria Epidemic.**—The study of this epidemic by Perkins and Furrer emphasizes the importance of administering a prophylactic dose of antitoxin to all children on admission to a hospital; the necessity and value of taking cultures and making bacteriologic examinations; and the advisability of taking cultures from the nose as well as from the throat before discharging patients from quarantine. The nurse in attendance on a diphtheria case should not be discharged from quarantine until negative cultures have been obtained. Isolation, quarantine, disinfection and fumigation are found to be of little or no value in controlling an epidemic until a systematic search is made for latent infections among inmates.

48. **Malaria in Early Infancy.**—Beekel's patient was only 10 weeks old. He was a first-born child, had been breast-fed entirely and had been well except for the present illness. This began three weeks before, and had been marked by symptoms of feverishness, restlessness, quickened breathing, lessened desire for food, occasional vomiting and increased frequency of bowel movements. The infant was well-developed and well-nourished. His appearance was remarkable because of the extreme pallor; the normal skin tint was replaced by a lemon-yellow color and the visible mucous membranes were almost white. The breathing was from 50 to 60 times a minute with slight expiratory grunting and some movement of the alæ nasi. There was no skin rash. The throat and mouth were negative. The chest examination was negative. The spleen was easily palpable and hard, and extended 3 cm. below the edge of the ribs. The liver was 3 cm. below the costal margin. There was no visible peristalsis, and the abdomen was not distended. Two small glands were felt in the posterior cervical region and one in the left axilla. The stool was of an orange-yellow color. The blood examination showed: hemoglobin, 30 per cent.; white blood-cells, 14,800; red cells, 1,600,000. Examination of stained specimens showed a very noticeable variation of size of the red corpuscles with poikilocytosis and polychromatophilia and nucleated red cells in large numbers, while the presence in many corpuscles of bluish-gray, pigmented, slightly irregular bodies solved at once the question of diagnosis. Hyaline forms of the parasite, early pigmented forms, a few filling from one-third to three-quarters of the infected red cell, presegmenting and segmenting forms numerous enough to be easily found were all present. Both father and mother of

the infant were found to have suffered from malaria, the father at the age of 15, the mother when 12 years old, but to have been free from symptoms for some years. The spleen in each of the parents was just palpable on deep inspiration. The child received quinin bisulphate in solution, 1½ grains, three times a day, syrup of the iodid of iron in 2 drop doses, three times a day, was prescribed at the second visit, and was continued to the end of the second month The child recovered

55 **Pyelocystitis in Infancy**—Friedenwald's study is based on a series of eighty cases, derived from a large foundling hospital, it is made up largely of young infants many of whom suffer from nutritional disorders and among whom infections, particularly influenza, are very common In this series he found fifty eight females and twenty two males, tending to show that the disease is much more common among males than previously believed The youngest child was 11 days, the oldest 22 months Under one month there were three, from one to three months twenty five, from three to six months, twenty two, from six to nine months, fourteen from nine to twelve months, ten, and over one year, six patients Fifty four cases occurred between the first of December and the first of June The months of May, February and March had respectively thirteen, eleven and ten patients while June had none and October and November each three The colon bacillus was demonstrated in a number of this series The proteus bacillus was found twice, the *B lactis aerogenes* once During the year ending Feb 1, 1910, there were twenty two cases of pyelocystitis, one half of these occurred in the months of November, December and January, during a severe epidemic of grippe Fifty nine of the cases were directly preceded by either some infection or an acute nutritional disorder, while only seven occurred under observation which were not preceded by a previous serious disorder The fourteen remaining patients entered with this condition Twenty one cases were preceded by some infection of the respiratory apparatus, of which seven were influenza and two diphtheria, twelve others by otitis media, seven by alimentary intoxication, six by septic conditions five by enteritis follicularis four by stomatitis, two by active syphilis with profuse eruption and one each by tuberculosis and vaginitis Of twenty necropsies the kidney pelvices and bladder both showed pathologic changes in fifteen instances, three times the pelvices were alone involved once the bladder alone and in one instance there were no pathologic findings in the urinary apparatus although the child had had pyuria six weeks previous to death That the lesion can be a simple catarrhal inflammation which quickly heals was shown in a case in which the patient developing a pyelocystitis after an alimentary intoxication and dying seven weeks later of acute tuberculosis gave no pathologic findings in either pelvices or bladder

57 Abstracted in The Journal, July 2, 1910, p 48

59 **Nitrogen Metabolism in Healthy Infants.**—The study of nitrogen metabolism, which Hoobler presents, is a portion of a larger metabolism problem which involved the determination of the nitrogen, fat, sulphur, magnesium and calcium in the food, urine and feces covering a nine day period, divided into three periods of three days each. The child used for this study was a healthy, robust, vigorous infant of nine months fed from birth on modified cow's milk, who was admitted to the hospital for operation for the closure of harelip The child was fed on three different cow's milk mixtures These involved the use of (certified) whole milk, fat free milk and 16 per cent cream, all of which were secured from the Walker Gordon milk laboratory, and when modified represented a low fat, medium fat and a high fat formula. Specimens of each of the three types of milk were carefully analyzed The child was kept on a definite formula at least two days before being put in the metabolic frame, and was kept three days continuously in the frame and given the same formula, so that the feedings were of five days' duration, while the metabolism experiment covered the last three days of the period *After each three day period in the frame the* child was given a rest for about ten days before being put into the frame again, during which time he was fed on Walker Gordon certified whole milk This period of rest gave the child ample time to recover his normal activities before going into the frame again The urine was collected daily and the total nitrogen, urea, ammonia and kreatinin determinations were made the same day, as were also the tests for acetone, diacetic acid and beta oxybutyric acid and total acidity The urine was then placed on ice until the salts were analyzed The feces were collected in daily quantities, except in two instances, when forty eight hour periods were collected were dried over water bath pulverized and passed twice through a No 40 sieve and stored in glass containers until examined. The methods used for the nitrogen determinations with which this paper deals were the Kjeldahl method for total nitrogen, Folin's method for ammonia, Folin's method for kreatinin and Folin's method for urea Controls were made and repeated when necessary It was found that nitrogen is absorbed exceedingly well by healthy infants fed on cow's milk mixtures The per cent of absorption at varying ages is about the same, even though the intake of nitrogen per kilo differs greatly Nitrogen absorption is carried on equally well under low medium and high fat feeding The percentage of absorption varies little from day to day The proportion of the food nitrogen which is retained is about one third The percentage retained is about the same for the three ages discussed Retention takes place in about the same percentage, whether fed on low, medium or high fat Percentage nitrogen retained remains about the same, whether fed on low, medium or high proteid In high proteid feeding a larger amount of nitrogen is absorbed and eliminated, thus causing more work" to be performed by the infant than on a lower proteid feeding Body weight may diminish under a fair nitrogen retention Nitrogen is largely eliminated through the urine Considerably more than half of the nitrogen ingested is excreted in the urine A very small quantity is found in the feces The excretion of ammonia nitrogen was higher on "high fat" mixtures than on 'low fat" mixtures.

73. **Acute Epidemic Poliomyelitis.**—The author discusses in detail the symptomatology, diagnosis and treatment of acute epidemic poliomyelitis, including abortive measures. There is no apparent reason, he says, why inflammation should not yield to local depletent measures here as well as elsewhere. This can be accomplished in several ways, the first and most obvious being by thorough catharsis. This is best done with calomel and castor oil. Castor oil is the most efficient agent, aided by enemas containing glycerin and turpentine. Local counter-irritation may have some effect on the congestion and in connection with hot or cold packs should not be neglected. Among the drugs which act to reduce the spinal circulation the most efficient is gelsemium, which should be given in small but frequent doses, until the effect is marked, and continued until the motor excitation is controlled; in severe cases it may even be given until the eyelids droop and sight is perceptibly affected. The fact that after the administration of hexamethylenamin it may be demonstrated in the spinal fluid has led to its use in this disease. The only patient in this series who received it died within a few hours after its first administration and there has been no opportunity since to test it, but on theoretical grounds it would seem to be valuable.

89. **Curvatures of the Spine.**—Seeking a means of lateral suspension Rich constructed a frame, in which he can suspend a patient in a horizontal position, and is enabled to apply a plaster corset. The main upper shaft of the frame is provided with several sliding collars, each bearing pulleys and rope. A platform is provided for preparation at a lower level. Anyone could extemporize the affair with several pulleys attached to the ceiling. The patient when stripped in preparation is laced on the platform on his side, having the side of the greatest convexity down. With a piece of canvas four or five inches wide the body is raised from the platform with the pull against the main spinal curve. With the body weight thus suspended on a fixed point, that part above the fulcrum and that below have enough potential from their own weight more or less to correct the deformity. The point of the maximum curve is marked and the body suspended from that point. When the spinal curve is low dorsal, the head will have to be likewise supported. Thus, when all is in readiness and the suspension is enacted, most of the body weight will be pendant laterally at the maximum point of the curve. By thus supporting the weight of the torso in these hammocks the following things are accomplished: 1. There is correction of rotation from pressure on the ribs. 2. The wide diameter of the chest on the side of the curve, known as the "rotation," is narrowed by being compressed into the angle and two sides of V-sling. 3. After one or two hours of suspension, while the muscles are being overcome, there is evolved enough potential from the weight of the parts of the torso above and below the point of suspension to enforce powerful correction of the deviation of the spinal column. 4. The torso, without hampering appliances, is forced into a position of correction suitable for the application of a retentive apparatus. For several days Rich suspends the patient for an hour or two to accustom him to the correction before splints are applied continuously. He has been substituting for the cast a plaster "figure-of-eight," which maintains pressure on the great dorsal curve by counter pressure on the compensatory cervical curve and on the pelvis. This splint might accomplish its purpose by encircling the one side of the pelvis, but it is borne much better if both hips are included. When putting these casts on, Rich applies the plaster bandages liberally about the body as we used to in putting on the old jackets, taking pains to reinforce well over the track of the figure eight. When the plaster sets all the unnecessary areas are trimmed off. This splint gives a means of very good retention and allows free respiration and suggests further correction. In posterior curvatures the patients are suspended at the point of the greatest deflection, lying on their backs, allowing, however, several hours to elapse before applying the corset to insure muscular relaxation and consequent correction.

99. **Plaster of Paris as a Universal Dressing.**—Orr has been using a modified method of applying plaster of Paris which he believes fulfills all the requirements of successful fracture treatment. The results in his own cases have been such as to justify a recommendation of its wider use. The method consists of applying plaster to the fractured extremity in the following manner. Plaster bandages are first applied over a suitable protective dressing like sheet wadding to include the foot and extend up to within a few inches of the point of fracture, whether in the leg, thigh or hip. When this is well set, firm traction is made on the finished portion of the cast; if there is a tendency of the upper portion to sag, it can be supported at the point of fracture, while the upper end of the cast is applied, beginning within a few inches above the point of fracture and extending to the hip in case of leg fracture or up to the thorax in case of any fracture of the femur. This upper portion of the cast is now also allowed to set and the cast is complete except at the point of fracture. The relation of the fragments of bone can now be determined and the third part of the cast applied. When this has set, immobilization is perfect and the traction which has been kept during the application of the last section of the cast is maintained as permanent traction. Any degree of traction can be obtained in applying plaster in this way. The objection

usually urged to the application of this form of cast is that allowance must be made for swelling of the parts; if such allowance must be made, it can be accomplished by the use of sheet wadding or some other material under the plaster. Orr believes that when good traction and immobilization are obtained so much allowance need not be made for swelling. Most of the swelling which follows an injury of this character is the result, not of the injury itself, but of failure to secure fixation of the injured part. When there is failure to secure immobilization, there is continued irritation and continued pain and also constant swelling. If the injured extremity is put entirely at rest there is little or no pain and but little swelling. Of course certain injuries are associated with fractures which produce a considerable reaction, but fractures of the hip, thigh and leg, unless accompanied by severe injuries of the soft parts, seldom produce severe swelling. He firmly believes that plaster of Paris combined with a reasonable degree of professional care and skill can be used in any fracture or injury of the lower extremity, and that nothing can be accomplished with any of the usual mechanical appliances or splints recommended for this purpose, but that can be obtained more easily and more satisfactorily with plaster of Paris.

5. **Venereal Diseases.**—Of twenty patients treated by McDonagh with Ehrlich's "606," in only one was there albuminuria, which appeared a few days after the injection but did not last longer than twenty-four hours. Two individuals had a localized toxic edema of one buttock, which quickly resolved under frequent applications of lead lotion.

8. **Treatment of Vomiting After Chloroform Anesthesia.**—In Keay's opinion the cause of this vomiting varies in almost every case, and generally both the central nervous system and the stomach are at fault. The derangement may be chiefly central or chiefly local, but there is always some combination of the two. In very severe cases interference with the functions of the liver and general metabolism may be the cause. A nervous patient who has had a minor operation with short anesthesia feels violently sick, and the strenuous efforts to vomit can be distinctly heard through a closed door. A little mucus is the result. If an enema of bromid and chloral be given the violent retching ceases as the feeling of nausea disappears. If the patient has not been properly prepared for the anesthetic by low diet and tonic treatment, nausea and vomiting come on early, usually during the administering of the chloroform, and ceases, or are lessened in severity, when the stomach is emptied. This proves that with chloroform anesthesia the stomach is made irritable and wants rest. The rational treatment, therefore, for ordinary cases is: give nothing by the mouth for twenty-four hours till Nature has reasserted herself. Any foodstuff, however readily digested, if introduced into the stomach, will further irritate that organ. Thirst, which may be complained of, can be assuaged by saline enemata. When the tongue and mouth feel dry, rinsing out the mouth with aerated soda-water or lemon-water, either hot or cold, will relieve the condition.

The vomiting tends to be more severe when the anesthesia has been prolonged. The treatment for such cases is long draughts of strongly alkalin solutions aided by counter-irritation over the epigastrium. Bicarbonate of soda dissolved in hot water may be given by the tumblerful. Hot fomentations, poultices with or without mustard, blisters, or an ice-bag are all efficient counter-irritants for the epigastrium. Of these, hot fomentations or a light poultice are the best. It is often found necessary to use some medicinal means to cure the gastritis. Keay has found that a mixture of dilute hydrocyanic acid, bismuth and soda acts very well, and in some patients with a foul tongue, powders of rhubarb, bismuth and soda are useful. In all major gynecologic operations, attended with some degree of shock, whether due to excessive exposure of the abdominal contents, to great loss of blood, or to sepsis, the complicating effects of the anesthetic are more pronounced. After most abdominal operations flatulence is relieved by giving salines by rectum, from one pint to one quart every four hours, a rectal tube being left *in situ* for an hour or so between times. Rubbing the abdomen adds to the comfort of the patient; more vigorous treatment may be required, such as turpentine enemata. If the violent sickness still persists on the second day, castor oil or magnesium sulphate should be given by the mouth. Although these drugs are most often rejected a certain quantity stays down and will do good. If the bowels do not act in six hours an enema of soap and water will prove effectual. Peristalsis, which is failing under the stress of the constant sickness, can be sustained by rectal enemata of brandy and water and sips of brandy by the mouth.

When the vomited matter is hemorrhagic and resembles beef-tea dregs or coffee grounds, the patient should be stimulated by copious draughts of hot soda solution, and in addition a solution of adrenalin chlorid, m v to m x, in a teaspoonful of water, should be given by mouth. It stimulates the muscles of the stomach walls, blanches the dilated capillaries, and sets up regular rhythmical contractions of the stomach, which causes its contents to follow their natural course and to flow on into the duodenum. For the collapse accompanied by an exceedingly rapid pulse which sometimes ensues in cases of protracted and exhausting vomiting salines and general stimulants are much more effectual than cardiac stimulants even in very large doses.

9. **Open Method of Ether Administration.**—Barton has devised an inhaler which does away with the drop bottle and only permits the passage of air over the ether during inspiration. It is made of metal and consists of a chamber with an attachable face-piece. The chamber is cylindrical, being open at the top and having another opening about the junction of the middle and lower third communicating with the face-piece. It is lined with lint which is held in place by a clip. The lint dips down into the ether contained in the well at the bottom of the chamber; the amount of ether capable of being conveniently held in the well is about 2 ounces. This is continuously soaked up by the lint, which presents an evaporating surface of twenty or more square inches. The face-piece is of the Roth-Drager type and is fitted with an expiratory valve. This may be dispensed with in cases where valves are deemed inadvisable, or may be fixed in one of two positions, either between the chamber and face-piece, or into a metal cap which is made to fit the opening at the top of the chamber. The latter position gives a stronger vapor. As designed, the apparatus is intended for use with the patient's face turned to one side. Owing to the rotation of the face-piece on its attachment to the chamber it is equally available for a right or left position of the face. For the few cases in which an upturned face is necessary, Barton has added an angle-piece for joining the chamber and face-piece. Another accessory is a pneumatic pad for use with the face-piece on patients on whom it will not otherwise fit accurately.

24 *Treatment of the Insane H F. Watson

24. Treatment of the Insane.—During thirteen and a half months, treatment of the insane without the use of sedatives has been tried at the Renfrew District Asylum, Dykebar, near Paisley. The number of patients admitted during the thirteen and a half months was 304, of whom 148 were men and 156 women. There were eleven deaths (six men and five women); a necropsy was obtained in every instance. An unusually large number of cases of dementia were admitted. This is due to the fact that 66 per cent. of the admissions were of patients transferred from other asylums; the remaining patients were direct admissions. Since the opening of the asylum on April 8, 1909, no sedative of any sort has been given, no form of restraint has been employed, no patient has been under seclusion, no case of suicide has occurred; there was but one major accident, and when it occurred two attendents who were suspected of negligence were summarily dismissed The results have been sufficiently satisfactory without sedatives, and this method of treatment has afforded an opportunity of seeing cases under circumstances different from the usual in an asylum. Watson condemns the habit of giving sedatives in quantity and over prolonged periods to patients who evidently are able to do quite well without

On admission to Dykebar Asylum, the usual treatment in every acute case, unless contraindicated, is the following: Hydrargyri chloridum mitis—calomel—(6 grs.), followed in four hours by magnesium sulphate (6 drs). Afterward such patients get a mixture containing pulvis rhei, sodium bicarbonate and hydrargyri chloridum mitis This is made up in bulk and 1 teaspoonful given thrice daily, the dose of calomel being 3 grains a day. Every morning the patient gets a soap and water enema, which is made up with soft soap, as this is considered less likely to produce a rash. This treatment is carried out till all signs of gastritis, intestinal disturbance (even constipation), with toxic absorption have disappeared.

In certain cases the patient seems to approach a comatose condition after an enema; this is due to the fact that the enema washes away adherent mucus (often in catarrhal layers) from the intestinal wall, and allows more free absorption of the toxins which are present. To prevent this, oleum eucalypti, 5 minims, added to the enema has been found to lead to rapid improvement. Bleeding has been found of use in acute conditions of insanity. A needle is inserted into the median basilic vein, and 10 c.c. of blood are drawn off, 20 c.c. of a 0.85 per cent saline solution being then injected, this treatment being repeated every second day. This seems to be much more effective than administration of diuretics, and has the advantage of acting at once When there is atony of the intestine it is well to give tincture of nux vomica, 5 minims, thrice daily, and to keep this up for from four to six weeks When a sedative has been continued over a period of years the resistance of all the tissues is lowered.

26 *Infantile Scorbutus (Maladie de Barlow) A B Marfan.
27 *Non Tuberculous Pyosalpinx in Virgins P. Bégouin.
28 *Eczema in Infants. C Rocaz

27. Non-Tuberculous Pyosalpinx in Virgins.—Bégouin has encountered a number of cases of inflammation of the Fallopian tubes consecutive to appendicitis in virgins, but an actual pus tube from this cause is comparatively rare. The suppurating appendix was in contact with the right tube in one girl of 16, and he removed both together. In two patients, virgins of 16 and 32, he found actual pus-tubes, bilateral and closed, non tuberculous, and resembling in every respect those found in married women. An ovarian cyst had been diagnosed in one of the cases and in the other there were evidences of recurring appendicitis. Microscopic examination excluded tuberculosis and only anaerobic germs were found. He has been unable to find any record in the literature of such closed bilateral pus tubes in virgins, but he has found records of peritonitis consecutive to pyosalpinx in little girls and older virgins. Riedel reported that in nine out of forty-nine cases he found a pyosalpinx instead of the anticipated appendicitis as the cause of the peritonitis requiring operative treatment in little girls under the age of 10 and in two virgins, out of 348 laparotomies for peritonitis in women. The infection occurred probably by way of the vagina and uterus in Bégouin's cases at least, both the patients having noticed leukorrhea for some time, the secretions being brownish and malodorous in one case

28. Eczema in Infants.—Rocaz does not attempt local treatment of eczema in infants unless the child is vigorous and healthy. But dietetic and other measures to reduce production of toxins and to facilitate their elimination, and organotherapy to supplement insufficiency of certain glands with an internal secretion, benefit the general health and the eczema frequently subsides under them alone External measures should be applied very cautiously, especially if the eczema is of large extent. Only a small area should be treated at one time and very mild applications should be used at first, the general health being watched all the time. It is important to cure the eczema, he adds, on account of its injurious influence on the nervous system and general health, and the way the skin lesions invite infection The first indication is to get rid of all scabs and they can be softened with sterilized oil or with potato poultices applied for two or three days; the poultices are soothing in the very irritable forms. The same results may be obtained with gauze compresses under rubber tissue. Simple eczema does not require antiseptic dressings but in the impetiginous form very mild antiseptics may prove useful, mercury bichlorid 1 per 10,000 or per 5,000 or a mixture of 2 parts each of zinc and copper sulphate in 900 parts water. Phenol, he states, should never be used; infants seem particularly sensitive to its toxic action. The surface once cleansed, a mild, soothing salve is needed, vaselin with zinc oxid or lard with benzoin or, if there is much secretion, a dry dressing with a powder made of 30 parts talcum, 10 parts bismuth subnitrate and 5 parts zinc oxid. With this the lesion is kept constantly covered until the scab becomes too thick, when it is softened anew with a potato cataplasm and the dry treatment then recommenced To keep the children from scratching face and head, he slips a pasteboard cuff over each arm, with the cuff wide enough to let the children bend their elbows sufficient to play with their toys, but the elbows cannot be bent enough to reach the face Bathing does more harm than good, he continues, as it exaggerates the skin trouble, and is liable to spread the infection to points still free from lesions Baths should be given very cautiously and briefly The same dietetic and hygienic measures should be enforced for the woman nursing the child as for the child itself. A change of wet nurse seldom does any good after the eczema is once well established. The food should be supervised with special care to reduce all chances of infection or intoxication. The substitution of asses' milk for cow's milk was followed by the subsidence of very extensive eczema in one case in his experience, and it has often aided in the cure in other cases. Thyroid treatment has proved effectual in a number of cases in the last two years, while in other cases no effect was apparent In the cases benefited there was usually a history of a digestive intoxication or some cachexia Under the thyroid treatment there is usually an acute exacerbation which gradually subsides and by the end of a fortnight the skin begins to look normal and a week or so later, the eczema is cured or much attenuated In a few cases the eczema seemed to be aggravated by the thyroid treatment, it should certainly be reserved for the torpid cases, Rocaz declares, but when the eczema has resisted all ordinary measures, including the dietetic and hygienic, a trial of thyroid treatment is justified and benefit may result It is harmless he states, he gives the thyroid in substance and he has never witnessed any mishaps although he has applied it in a very large number of cases and over long periods in some of them This thyroid organotherapy has proved useful for fat babies with an inherited rheumatic taint, as this 'arthritic diathesis" is liable to be accompanied by thyroid insufficiency

32 *Clinical Diagnosis of Tuberculous Appendicitis F Lejars

32 **Tuberculous Appendicitis**—Lejars reports several cases of acute tuberculous processes in the appendix with or without tuberculous or ordinary peritonitis The patients were between 20 and 32 and the feature common to all was the distention of the abdomen ushering in and persisting after the acute symptoms In other cases the appendicitis was an ordinary inflammation but was embedded in a focus of tuberculous peritonitis In another group of cases an acute tuberculous peritonitis simulated ordinary appendicitis In one such case the incision in the iliac fossa showed that the omentum, cecum and appendix were studded with miliary granulations, but there was no ascites or abscess, and he sutured the abdomen without removing anything but a scrap of omentum for microscopic examination Contrary to expectations this exploratory laparotomy seemed to usher in a turn for the better In this tuberculous peritonitis with localization mainly in the iliac fossa the acute phase is often brief, the pulse remains good and the temperature drops soon, in marked contrast to the great distention of the abdomen suggesting diffuse peritonitis Evacuation of the ascites and removal of the appendix at need will generally arrest the acute phase while exerting a beneficial influence on the tuberculous peritonitis as a whole Chronic tuberculosis in this region should be suggested by the contrast between the size and extent of the non limited tumor in the iliac region and the absence of fever and of any noticeable reaction Ascites should also suggest a tuberculous process, especially if persisting Differentiation is important on account of the prognosis

Beitrage zur Klinik der Tuberkulose, Wurzburg

XVII, No 3, pp 281 480 Last indexed Nov 5, p 1688

33 *Experimental Research on Tuberculosis Immunity and Prophylaxis P H Romer and K Joseph

33 **Experimental Research on Tuberculosis**—This entire issue of the *Beitrage* is devoted to the report of years of research at the Institute for Hygiene and Experimental Therapy at Marburg, bearing on the questions of reinfection with tuberculosis, experimental infection of suckling animals with tuberculosis and resulting immunity, the nature of immunity to tuberculosis and studies of antibodies, the etiology of pulmonary phthisis and the practical means to combat the spread of tuberculosis, and research on the various tuberculin reactions and on *hypersusceptibility to tuberculin* These questions have been studied in experiments with guinea pigs and sheep, the latter were found peculiarly adapted for the research The main fact which Romer and Joseph were trying to establish and which they now affirm has been demonstrated beyond question, is that one infection with tuberculosis confers a certain protection against further infection from the tubercle bacillus Among their other conclusions is one to the effect that in the circles where tuberculosis is most prevalent scarcely any child escapes the infection Consequently pulmonary tuberculosis in the adult develops in the overwhelming majority of cases in an organism already infected since childhood There is every reason to assume, they say that the law which governs tuberculosis in animals applies also to man, namely, that infection with tuberculosis confers immunity to further tuberculosis infection to the extent that small amounts of the infecting virus have no action on the already tuberculized system but rebound making no impression When large amounts of the infecting virus come into play this protection is inadequate to save the individual completely, but the superposed infection is modified so that it does not assume the form of galloping consumption as in the previously non infected but runs its course as chronic pulmonary tuberculous disease One of the practical consequences of this view is that it is important to distinguish between tuberculous infection and actual tuberculosis Much would be gained, they declare if efforts were directed more to prevention of phthisis rather than prevention of tuberculous infection To combat consumption effectually requires prevention of infection in children or prevention of the possibility of massive reinfection additional infection Efforts to combat the spread of tuberculosis should be concentrated more on the children to save them from the threatening infection against which they have as yet no specific means of defense The "inherited taint" is *nothing* the authors declare, but the severe infection acquired in the tuberculous family during early childhood As no source of tuberculosis infection *could* be discovered for half of the children who gave a positive response to the tuberculin test in Hillenberg's research, it seems evident that the tuberculosis virus exists in some mild permanent form in countries where tuberculosis has long been endemic, and permits what Andvord calls a beneficent vaccination against the disease Experiences with cattle have shown that the strictest hygiene has no influence in preventing the spread of tuberculosis among them There is only one thing that will do this namely the separation of the diseased from the well animals Everything points to the importance of concentrating our efforts on the child keeping it away from all contact with tubercle bacilli sowing consumptives either by removing the child from contact with the consumptive, or by isolating the consumptive or maintaining at least a relative isolation Romer and Joseph suggest the possibility of conferring immunity on children by appropriate vaccination and thus aiming them directly against the bacillus This protective vaccination has been successfully worked out for guinea pigs but it is another question whether it would prove equally harmless and equally effectual for human beings, and whether its application would ever be practicable

34 *The v Pirquet Tuberculin Reaction in the Non Tuberculous F Dumont

34 **Cutaneous Tuberculin Reaction in the Non-Tuberculous**—Infants with eczema seem to respond to the v Pirquet skin tuberculin test, even when they are apparently free from tuberculosis, and this excessive sensitiveness to the test is sometimes encountered under other conditions A second inoculation will generally clear up the diagnosis, as the really tuberculous are liable to give a stronger reaction the second time, while in the non tuberculous the second attempt elicits

a much weaker response, if any. The skin is sometimes found insensible to the action of the tuberculin; this is encountered most frequently in young infants. In a few cases on record the child responded with such intensity to the skin test that ulceration followed, and Karrer reports a case of this kind from his own experience. The patient was a boy of 13 who had lost his appetite, looked bad and tired easily but there were no local findings in the lungs or glands and no cough. The inflammatory reaction to the v. Pirquet inoculation of tuberculin was unusually intense, the arm swelled and ulcerated, the nostrils showed eczematous infiltration and the eyes were inflamed for a few days. By the end of three weeks a diffuse itching erythem developed, soon followed by more papulo-necrotic processes. The new papules that formed looked like the primary Pirquet papules, and the whole syndrome was evidently the result of a specific hypersusceptibility on the part of the skin. This case resembles the two reported by Bruck in lupus patients who developed a morbilliform eruption a few hours after the v. Pirquet test had been applied. The eruption recurred again after a second inoculation a week later. In the second case the reaction to the test in a boy of 8 was the ordinary positive response, but a second injection a week later elicited an eruption resembling that of scarlet fever, with conjunctivitis and swelling of glands. The exanthem gradually subsided with desquamation. Animals injected with the blood of these patients, followed by injection of tuberculin, rapidly succumbed, confirming the assumption that the explosive reaction was due to a specially large proportion of anaphylactic antibodies in the blood of these two patients.

37. **Ehrlich's "606" in Syphilis.**—Zieler mentions that hemoptysis seemed to have been brought on by the injection of "606" in a case of secondary syphilis with concomitant apical tuberculosis, and he warns that this possibility should be borne in mind. In tertiary syphilis the action of the new remedy did not seem to surpass that of mercury, and in some cases was distinctly inferior. Its special field, he thinks, will be in cases refractory to mercury, but here the "606" is liable to fail also. With recent syphilis the "606" seems to act more rapidly and with greater intensity than mercury, he says, and the fact that it is impossible to kill all the spirochetes at one stroke is of minor importance. Ehrlich's hope that this might be accomplished has already been realized with relapsing fever.

Medizinische Klinik, Berlin

45 *Ehrlich's "606" in Syphilis. W. Fischer.
46 Benzidin Test for Blood. (Zum Nachweis geringer Blutmengen mit der Benzidinprobe.) J. H. Greeff.

43. **Operative Treatment of Constipation.**—Goebell states that he at first regarded valvotomy in treatment of constipation as another example of "American humbug," but has since found that this operation has a logical basis, and during the last two years has applied the method in six cases, slightly modifying Gant's valve-clamps, so that they can be held better by the rear and can be applied slanting at need. In his first five cases the abnormal development of the rectal valves readily explained the difficulty in rectal functioning and the division of the valves put an end to the chronic constipation. The patients were three men between the ages of 20 and 47 and two women between 21 and 27. In another case, in a woman of 26, four valves were seen in the rectum. A movable cecum was first corrected and then one of the four valves in the rectum was divided with the actual cautery. The constipation is much improved but there is still an occasional tendency in this direction. He advocates operative treatment of anomalies in the position, length and size of the large intestine, as all such anomalies are fraught with grave dangers, volvulus being liable to develop at any moment with a movable ascending colon or unusually large colon. He recently had to operate on a woman of 75 for torsion of an abnormally long sigmoid flexure, showing that age is no protection against this eventuality. In two cases he corrected an abnormally movable ascending colon and right flexure by fastening the posterior wall of the bowel to the parietal peritoneum. In three other cases he corrected conditions merely by dividing congenital peritoneal cords binding down the flexure. In one case the intestines became occluded from adherence of the omentum to the spleen after typhoid; in another case adhesion of the omentum to the spleen and diaphragm caused a train of symptoms diagnosed as cancer. The defect left by releasing the omentum was remedied by suturing the gastrocolic ligament over the defect and suturing the appendices epiploicæ to the stomach in place of the gastrocolic ligament. There has been no recurrence of the previous chronic syndrome which included alternating constipation and fetid diarrhea and colic. Recurring colic-like pains or local tenderness relieved by defecation point to some hindrance to the permeability of the bowel, and the favorable results reported above encourage, he thinks, exploratory laparotomy when nothing can be found otherwise to explain the chronic constipation. He is inclined to advise appendicectomy in every case of constipation with pains in the ileocecal region, even when the appendix is apparently sound; any tendency to undue movability on the part of the colon or abnormal size of the sigmoid flexure is revealed by the incision.

44. **Tuberculous Hydronephrosis.**—In the case reported by Kroiss a young woman complained of pain in the right knee radiating to the groin but seemed otherwise in good health; the urine was normal. The physician examining her discovered a large tumor in the right side of the abdomen of whose presence the patient was entirely unaware. Operation revealed a closed right hydronephrosis with tenacious adhesions; in removing the kidney it tore, flooding the wound with nearly two liters of fluid. The microscope revealed signs of tuberculosis in the kidney, and generalized miliary tuberculosis soon developed, proving fatal in two months after the operation. There had been nothing to indicate tuberculosis in this case before the operation, everything indicating a closed aseptic hydronephrosis. If the possibility of tuberculosis had been thought of, the sac might have been drained by puncture before the nephrectomy was attempted, and thus the wound would not have become contaminated with the infectious fluid. Krauss has reported a similar case but no general infection resulted; Rochet has recently reported three cases of tuberculous wound infection during nephrectomy, but the ultimate outcome was favorable. Kroiss adds that in another case in his own experience a teaspoonful of urine from the kidney pelvis escaped into the wound as the ureter was divided, and miliary tuberculosis followed in this case also. Kocher has informed him of a similar experience, the infection in this case proceeding from the cauterized stump of the ureter. The data related emphasize the necessity for bearing tuberculosis in mind in all operations on the kidney, even when there is nothing to suggest its presence. The findings suggested that the closed hydronephrosis was only secondarily infected with tuberculosis.

45. **Ehrlich's "606" in Syphilis.**—Fischer states that Buschke, to whom he is assistant, declares that his extensive experience with the new remedy in the dermatologic department of the Rudolf Virchow hospital at Berlin has convinced him that it should be reserved exclusively for patients refractory to mercury. He has also encountered a few patients refractory to "606," and prolonged observation is showing that even when the primary manifestations have subsided under its influence, general symptoms are liable to develop later. The lesions which subside so rapidly under the "606," he continues, are the kinds which promptly subside under any

method of treatment or without it, the indurated chancres being more slowly influenced. In one such case the chancre was found nearly the same size and swarming with spirochetes two months after the injection of the usual dose of "606," while the patient has been tormented since with extremely frequent and severe colic pains, never observed before, and which Buschke ascribes to the arsenic. He says that no one seems to appreciate how rapidly syphilids may subside under ordinary treatment; clinicians are surprised by the rapidity of the action of the "606" when, if they will keep records of the cases in which mercury alone was used, they will frequently find that the syphilids disappear as fast or even faster under mercury. In a recent case a much debilitated man had numerous syphilitic ulcerations over his body, especially on the legs, with papulous syphilids on the back, and positive Wassermann reaction. Under salves and baths the ulcerations all healed over in twelve days and then mercury was commenced, under which the papulous syphilids soon healed. The man gained six pounds in the three weeks. The tonic effects of the care and food in the hospitals have often an amazingly favorable action on the general health without any drugs or under mercurial treatment. But the "606" has displayed great efficacy in the severe and extensive syphilis refractory to mercury, and this seems to be the special field of the new drug, although it may fail even here, as in a case Fischer has previously reported.

Syphilis of the central nervous system also seems in certain cases to be amenable to the new drug, but special caution is required here as cases have been reported in which no benefit or actual harm has followed its use; even fatalities have been reported. On the other hand, calomel renders good service in these cases, especially in the recent cases. Recurrences after "606" have been frequently reported but the question now is as to whether the recurrences are exceptionally mild or not. In four cases in Fischer's experience the recurrences were unusually early and unusually intense; in one case the symptoms indicated meningeal irritation. In a fifth case the symptoms suggested arsenic intoxication but they might have been explained by some incipient syphilitic cerebrospinal trouble, but other symptoms suggested hysteria and an epileptiform seizure and weakness of the right leg further complicated matters in respect to the share of the "606" in the syndrome. No methyl alcohol had been used in injecting the "606;" Rille and Spiethoff have also reported epileptiform seizures after its injection. In five other cases in which "606" had been injected on account of skin lesions, recurrence was observed taking the form of serious specific iritis in four and of neurochorioretinitis in the other. He knows of a number of similar cases observed by others, the recurring manifestations developing in the eyes. There was no predisposition on the part of the eyes in any of these five cases, ophthalmologic examination before the injection of "606" having shown normal conditions. He thinks that the new remedy probably has a special affinity for nerve tissue, and although it does not directly injure the nerve, like atoxyl and arsacetin, yet it provides a place of lessened resistance and here the syphilitic virus preferably locates—a syphilis *ex trauma*.

Rille and Pinkus have recently reported three cases of jaundice following administration of "606." The local necrosis sometimes observed is evidently of purely chemical nature; it is exceptionally torpid, and operative removal of the necrotic tissue is practically impossible as the necrosis goes very deep, the chemical action extending far into the interstices in the tissues. The breast is a particularly unfavorable point for the injection on this account; in one patient the necrosis in the breast extends down and into the ribs and there is danger of perforation of the pleura. Only a part of the arsenic seems to be taken up into the tissues; the rest is slowly, possibly intermittently eliminated, and these factors vary in different individuals so that it is unusually difficult to determine the tolerated dose. Fully as good therapeutic results have been observed with small as with large doses. Alt and Hoffmann have reported severe symptoms on the part of the heart after the injection of the new drug, and Fischer reports another grave case of the kind. The patient was a young man, healthy until infected with syphilis early in 1910.

47. **Fluctuations in the Resisting Power of Bacteria.**—Stern remarks that the changes in the body during the course of an infection have been well studied, but not much is known of the changes which the invading bacteria themselves undergo in the course of the infection. His research seems to show that the ability of the bacteria to withstand the defensive reactions of the body varies widely at different times and under different conditions. Typhoid bacilli, for example, cultivated directly from the blood of a typhoid patient are sometimes unaffected by the usually bactericidal blood-serum, while the same strain cultivated through a few generations outside of the body is rapidly destroyed by the serum. This fact explains the varying action of different bactericidal serums: they prove effectual on animals—the animals being inoculated with artificially cultivated bacteria—while in man the same serum is liable to prove inactive against the invading bacteria as they have acquired resisting powers in the course of the disease process they have set up in their host. For example, if 30 grains of hexamethylenamin are given in one dose to a healthy individual, his urine kills in a few hours typhoid bacilli added to it outside. This also occurs with urine from certain persons with bacteriuria, cystitis or pyelitis, but in other cases in this same category the urine does not acquire any bactericidal property even under a prolonged course of large doses of the drug. This occurred in three out of eleven cases of cystitis and pyelitis in his experience. It is possible that the diseased mucosa secretes some substance which acts on the bacteria, rendering them hardier.

48. **Influencing of the v. Pirquet Tuberculin Reaction by Various Diseases.**—Rolly reports experiences showing that in the course of various infectious diseases the tuberculin skin test may elicit a negative changing to a positive reaction during convalescence even in the absence of tuberculosis. He presents arguments to show that this is due not to some general immunity process but rather to local modifications in the skin itself.

49. **Clinical Importance of Lime.**—Meyer has been studying in various ways the action of lime in the organism, and states that one of the best ways to obtain an insight into the action of a certain element in the protoplasm is to study what happens when this element is rendered inactive. This can be done in respect to lime by giving oxalic acid, which seems to draw the lime out of the tissues or else to bind it or in some other way to render it inactive or nullify its action. Januschke has found that experimental oxalate intoxication—not only the toxic paralysis of the heart but also general intoxication—can be arrested by administration of lime or strontium salts. This does not occur when barium salts are given although the latter are able to bind the oxalates *in vitro* as effectually as the lime salts. The effect is due not to the binding of the oxalate but to the supplying of the tissues anew with lime to replace that which has been drawn out of them by the oxalic acid. In every intoxication from an acid the lime is drawn out of the tissues, he asserts, and the lime content of the blood increases. Among the symptoms of oxalic acid intoxication are salivation, alternate maximal dilatation and contraction of the pupil and alternations of a very high and very low blood-pressure—all suggesting increased irritability on the part of the nervous system from partial loss of the

lime content of the nerve tissue. This assumption is confirmed by the increased sensitiveness to suprarenal extract of the organs innervated by the sympathetic system, as well as by the subsidence of the symptoms under administration of lime. Another phase of the physiologic action of lime has been shown by the different behavior in respect to exudates and transudates when animals are given lime. The effusions and edematous transudates observed in animals after inoculation with diphtheria toxin, mustard oil, etc., do not occur in animals previously treated with lime salts. This suggests that the increased proportion of lime in the body has rendered the vessel walls less permeable. This assumption is further confirmed by the experiences with experimental exanthems with effusion, easily induced in the non-treated animals but failing to develop in the animals previously given lime. Wright ascribes this to increased coagulability of the blood under the influence of the lime salt, but Meyer thinks that it is much more likely to be the result of changes in the walls of the vessels of the skin. The same explanation applies also to diarrhea, the result of abnormal permeability of the intestinal vessels. The research reported supplies a physiologic foundation for the sedative action of lime on the organic nervous system and for the correction of the tendency to effusions and transudates by lime salts rendering the vessel walls less permeable.

50. **Fluctuations in the Blood-Pressure.**—Zabel has found that the blood-pressure even in the healthy fluctuates within a wide range from apparently insignificant causes. Stimuli of all kinds are liable to raise or depress the blood-pressure temporarily. Certain persons are more instable in this respect than others, and the variations in the blood pressure are liable to mislead in diagnosing unless the possibility of these fluctuations is borne in mind. The lowest average pressure in fifty measurements on the same individual under like conditions supplies a reliable standard—the pressure measurements taken first vary widely.

51. **Advantages of the Transverse Laparotomy Incision.**—Jaschke concludes from experience with the Pfannenstiel transverse incision in over 1,000 cases that the ultimate outcome is much better with this than with the longitudinal incision, even in cases with dubious asepsis. The tendency to postoperative hernia is less, the patients are able to be up earlier and the scar is less prominent. Button sutures are preferable as infection, if it occurs, remains localized to the one suture instead of running along the continuous suture. It should be fine and the superficial sutures or clips should be removed early; when the lips are not adhering by the fourth or sixth day, primary healing need not be anticipated and clips too close together and left too long may impede the escape of secretions.

59. **Paratyphoid Simulating Criminal Poisoning.**—Mayer reports a case in which a man cut his throat after a brief period of vomiting and diarrhea, and the family circumstances, involving property, suggested criminal poisoning that had induced mania. Necropsy revealed merely an early stage of paratyphoid infection. He has encountered three other cases of incessant cholera-like vomiting and diarrhea fatal in two days for which paratyphoid infection was responsible. A small epidemic of similar cases occurred at Kotbus in 1905. The enormous loss of fluids exhausts the patients to such an extent that the assumption of acute poisoning is almost inevitable, especially as the mind is not affected as with typhoid.

62. **Action of Ehrlich's "606" on the Blood.**—Bardachzi and Klausner found an increased proportion of urobilin in the urine after injection of the "606" in a number of patients, but the most striking effect was a remarkable transient increase or decrease in the red blood-corpuscles which was regularly observed in the patients whose blood was examined. The number of reds varied by nearly or over 1,000,000 in the seven cases cited, running from 5,750,000 up to 7,300,000 in one case in twenty-four hours and dropping from 4,800,000 to 3,800,000 by the evening of the day of the injection in another case.

65. **Fascia Transplantation in Treatment of Paralysis of the Trapezius.**—Rothschild reports a case in which he realized a complete functional cure of severe paralysis of the right trapezius by a free plastic operation. The paralysis was the result of injury six months before and the patient was unable to use the arm at all, but in ten days after the operation neither the patient nor the physician was able to detect any functional difference between the use of the injured and the sound arm and the cosmetic result was equally good. The scapula is a little farther from the spine than its mate, but the two are level and the inner margin is parallel to the spine. This was accomplished by cutting a flap from the wide dense sheath of the chief muscle of the thigh, about 20 cm. long by 4 or 5 cm wide, and suturing the narrower end to the inner margin of the scapula above its spine, and then, as the scapula was forced towards the spine and downward by an assistant, the other end of the flap of fascia, drawn taut, was fastened to the latissimus dorsi and the lower longissimus, close to the spine. The fascia pulled on the scapula with such force that the latter was drawn up to a level with its mate, and its inner margin ran parallel with the spine. In order to leave the scapula some freedom of motion, the flap was sutured to the muscles which yield a little, rather than to the vertebræ, for the inner point of fixation. The end sutured to the scapula was made purposely narrow so as not to interfere with the normal twisting of the scapula in certain movements. In order to prevent the growing of the fascia to the skin, he passed the flap through a slit in the trapezius and let it run under the longissimus dorsi. The strong traction and the eccentric insertion of the flap of fascia leave the scapula practically as free as when it was under the control of the trapezius.

66. **Resection of Stomach and Colon.**—In the case reported, the cecum, ascending colon and its flexure were totally excluded after resection of the stomach and appendicostomy. The operation was done for carcinoma and the patient left the hospital in good condition.

74. **Tubercle Bacilli in Mucus from Infants' Larynx.**—Blume's method of obtaining mucus from the larynx as an aid to the diagnosis of tuberculosis was mentioned in The Journal, Aug. 21, 1909, page 664, with instances of valuable information thus obtained which had escaped all other means of investigation. He here reports the application of the method to very young infants long before any of the tuberculin skin reactions could be elicited and before expectoration was possible. It is easier to obtain the mucus from the larynx of an infant than from an adult. The child gags as the index finger of the gloved left hand is introduced far back into the mouth; it is then easy to wipe up cautiously a scrap of mucus from the larynx with the cotton swab. In six cases reported in detail in hygienic, wealthy homes or in an institution, the suspicion of possible contact infection was confirmed by the finding of tubercle bacilli in the mucus, in one case only twenty-eight days after birth. He expatiates on the importance of an early diagnosis, citing Neisser's practice of testing with tuberculin all his lupus patients since he witnessed extensive tissue destruction and blindness in a mother and daughter in the course of supposed lupus, which later proved to be of syphilitic origin. Pontoppidan has also published cases of tuberculous meningitis in adults which were incorrectly treated on the assumption of delirium tremens. Liebermeister also obtained positive results in inoculation of guinea-pigs in three out of five cases of supposed alcoholic neuritis. Blume also reaffirms the extreme importance of the amount of tuberculous virus with which the individual is infected, suggesting that infants alone are able to contract infection from the mild cases, while adults escape. He also discusses further Nature's "beneficent vaccination," to which some ascribe the modification of the course of tuberculosis in recent decades, as in Denmark, for example, where tuberculosis is far more prevalent now than it was up to 1870, while the mortality has reached the lowest recorded percentage, pulmonary phthisis growing rarer every year. He does not believe that we have Nature to thank for this. "Nature," he says, "is a poor vaccinator; her vaccine-virus is more virus than vaccine." If it were otherwise, and if all were properly vaccinated by Nature in early childhood, then the tuberculin reactions would be growing less frequent among adults, while in reality the opposite is the case.

77. **Therapeutic Inhalation of Oxygen.**—Tøndering tabulates the details of forty-five cases of asthma with or without pulmonary emphysema, of chronic bronchitis, neurasthenia with insomnia or simple anemia, in which marked improvement was realized under treatment by inhalation of oxygen in all but two instances, and no harm resulted in any case. The oxygen was inhaled at first for twenty minutes a day and after a week or so was combined in some cases with instrumental artificial respiration.

METABOLISM IN DIABETES*

GRAHAM LUSK
NEW YORK

"When Bernard had completed his lectures in the winter term of 1854-55, few questions in physiology were apparently more completely settled than that of the glycogenic function of the liver. The consequences of this doctrine were of the utmost importance, for, once settled that sugar is the product of animal as well as vegetable organisms and that an organ can be found which is singly concerned in its production, we would have at once in the exaggerated performance of a normal function, the proximate cause of diabetes. There had been from the first no lack of opposition to Bernard's views, but so skilfully had he defended his position that, at the time of which we make mention the very objections of his critics had only served to increase, in the eyes of the candid, the magnitude of his triumph."

These were the opening words of an article on "The Origin of Diabetes with Some New Experiments Regarding the Glycogenic Function of the Liver," read before the Medical Society of the County of New York forty years ago by my father,[1] then professor of physiology at the Long Island Medical College. The paper controverted the stand taken by Pavy, and held by him to this day—that the conversion of glycogen into sugar is a post-mortem phenomenon. The paper showed that blood drawn by a catheter from the right heart of a resting dog which had been fed on meat was four times richer in blood-sugar than that contained in the jugular vein, and from this it was inferred that the hepatic vein was carrying sugar into the venous system. The discussion which followed the reading of the paper was opened by Dr. Austin Flint, Sr., who stated that he had two diabetic patients in whom regulation of the diet had been the only and successful treatment. Dr. Austin Flint, Jr., then described experiments he had made on the glycogenic function of the liver and gave a lucid interpretation of them.

I have made mention of this scene to illustrate how forty years ago in New York City the spirit of research was active in the lives of two young men then about thirty years old, while the older master of medicine stood by in sympathetic encouragement. It is thus that the science of medicine is developed, and that young men who subject themselves to like discipline become powerful.

In this paper of my father is noted the fact that other organs besides the liver might be involved in diabetes, and indeed in one case which he had examined the only lesion he could discover was calcareous degeneration of the pancreas.

In 1889 von Mering and Minkowski extirpated the pancreas of dogs and produced in them a so-called "total diabetes" which bears striking resemblance to human diabetes. Dogs with pancreas diabetes cannot oxidize dextrose when given; dextrose is produced from protein so that 2.8 gm. of dextrose appear in the urine for each gram of nitrogen; there is acidosis with the appearance of beta-oxybutyric acid in the urine; there is emaciation and finally death in coma. Minkowski maintains that disease of the pancreas is the cause of diabetes mellitus. Lépine's suggestion that the pancreas manufactures a ferment which, passing to the blood-stream, *effects the oxidation of dextrose within the cells of the* normal organism, gave a simple though by no means proved explanation of the influence of the pancreas over carbohydrate metabolism. Cohnheim's explanation that the pancreas furnishes a "kinase" or activator which influences a second glycolytic ferment, is an elaboration of Lépine's idea.

The influence on diabetes of glands other than the pancreas has recently attracted considerable attention, but the results obtained by different experimenters have been so conflicting that considerable doubt exists as to whether they have any action at all.

In work on a diabetic patient, a medical student under strict control, Arthur Mandel and I found on a meat-fat diet that 3.65 gm. of dextrose appeared in the urine for every gram of nitrogen present there, and this was a relationship which I had for many years obtained in phlorhizin-glycosuria in dogs. This relationship between the dextrose and the nitrogen in the urine, the so-called D:N ratio, is a matter of considerable importance in the modern literature of diabetes. All those present remember from their early instruction in physiology that the appearance of 1 gm. of nitrogen in the urine corresponds to a destruction of 6.25 gm. of protein in the organism. On the basis of the experiments on the diabetic medical student we can therefore establish the following equation:

6.25 gm. protein = 3.65 gm. dextrose = 1 gm. nitrogen.

In other words, protein yields nearly 60 per cent. of itself as sugar. This relationship was constant, no matter how much protein was given, and was in no way dependent on variations in the amount of fat ingested. I am fully aware that authorities for whom I have a profound respect proclaim that fat may be converted into sugar in the metabolism of the diabetic, and to such assertions I can only reply that I have never seen any evidence of it.

---

* Read in the joint meeting of the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology of the American Medical Association, at the Sixty-First Annual Session, at St. Louis, June, 1910.

[1] Lusk, W. T.: New York Med. Jour., 1870, xi, 506; discussion on p. 565.

Regarding the origin of sugar from protein, it is certain that it does not arise from sugar pre-existing in the protein molecule. Protein is made up of many nitrogen-containing organic acids. When these are broken up in metabolism they yield ammonia, which unites with carbon dioxid to form ammonium carbonate and is carried by the blood to the liver and there converted into urea. Some of the organic acids which have lost their nitrogen are carried to the liver and are there converted wholly or in part into dextrose. Such an organic acid which arises from protein after this fashion is lactic acid, which when carried to the liver is synthesized to dextrose. This illustrates the principle of sugar production from protein.

Our patient, the medical student previously referred to, had no tolerance for carbohydrate. His sugar output approximated N grams in urine × 3.65 + carbohydrate ingested. That is to say, the urine of one day during which he had received a diet of meat and fat and 185 gm. carbohydrates amounted to 2,870 c.c., containing 217 gm. or 7.5 per cent. of sugar derived as follows:

17.8 gm. N × 3.65 gm. = 65 gm. dextrose from protein + 152 gm. extra dextrose.

And then two days later on a diet of meat and fat and only 5.5 gm. of carbohydrate, the urine amounted to 2,275 c.c., containing 92.6 gm. or 4 per cent. of dextrose derived as follows:

24 gm. N × 3.65 = 87.6 gm. dextrose from protein + 5 gm. extra dextrose.

The condition of the patient was the same on both of these days and yet how different the quantity of dextrose voided, and how different the percentage of sugar!

The figures show how utterly fallacious is the customary habit of the clinician in estimating the intensity of diabetes in accordance with the percentage of sugar contained in a twenty-four-hour sample of urine. And yet my own students, who should know better talk to me about a "2-per-cent. urine," and then suddenly realizing the situation look at me with a sheepish countenance. There are others who draw conclusions of disturbed protein metabolism from a knowledge of the number of grains of urea in an ounce of urine, without realizing that this is of no more importance than a knowledge of the number of ten-penny nails to the ounce of nails.

No, the intensity of diabetes should not be determined by the percentage of sugar in the urine, but by the relationship between the in-go of sugar plus the possible maximum of sugar production from protein as compared with the total output of sugar. This may be illustrated in the following formula modified from that given by Falta.[2]

$$\frac{\text{Output of dextrose}}{\text{Urine N} \times 3.65 + \text{food-dextrose}}$$

This multiplied by 100 gives Falta's "coefficient of excretion," or the per cent. of sugar eliminated.

In other words, recognition must be given to the fact that the output of dextrose is dependent on the amount of carbohydrate ingested and also on the height of the protein metabolism.

In diabetes the protein metabolism is higher than under normal conditions. This is because the oxidation of carbohydrates normally reduces the quantity of protein metabolized in the body. This is generally recognized as a fundamental fact of nutrition. The recent literature has contained examples of nitrogen equilibrium maintained on diets containing only 8 and 10 gm. of nitrogen, and such a low protein diet has found its advocates.

It may well be that 10 gm. of protein in the diet of an already emaciated diabetic may be sufficient to maintain him in nitrogen equilibrium in the reduced protein condition in which he finds himself, but this does not by any means invalidate the general principle that *the diabetic organism cut off from the ability to oxidize carbohydrates requires more protein food than the normal organism.*

There is a second phase of disturbance in the metabolism of the diabetic, and this is an imperfect oxidation of fat. Theoretically each fatty acid contained in fat and some of the oxy-acids produced when protein breaks up may yield a molecule of beta-oxybutyric acid. The diabetic organism thrown as it is on its fat-burning ability to support its life may find its capacity in this direction also curtailed. Under these circumstances beta-oxybutyric acid, acetone and aceto-acetic acid appear in the urine. This is the cause of diabetic acidosis. The urine runs high in ammonia, withdrawn to neutralize the acids formed. Alkali may also be taken from the body for the same purpose. It was Friedrich Müller who first drew attention to the fact that the percentage of ammonia in the urine had little significance, whereas the number of grams eliminated daily was an approximate measure of the intensity of the acidosis. He stated that the normal elimination of ammonia varied between 0.3 to 1.0 gm., but in diabetes reached 2, 6 and even 12 gm. in twenty-four hours. Klein and Moritz[3] have recently shown that ammonia and fixed alkali normally serve one and the same purpose, i. e., the neutralization of acids which are being eliminated. These acids are organic acids and inorganic phosphates. They find that large amounts of sodium bicarbonate given to normal persons may reduce the quantity of ammonia in the urine to almost nothing. Such a urine, while alkaline to litmus, is acid to phenolphthalein, the excess of alkali appearing as sodium bicarbonate and as secondary phosphate. They also find that increased ingestion of fat results in the elimination of alkali from the body on the day following the fat administration, a result they explain as being due to the necessities of fat metabolism. From this it may be concluded that administration of sodium bicarbonate in diabetes prevents the withdrawal of alkali from the body in the preliminary formation of soaps in the intestine, and secondly, promotes the elimination of the acids formed in metabolism.

Reviewing the ground traversed, one appreciates that one is dealing in total diabetes with an organism with no carbohydrate metabolism, with a high protein metabolism, with a more or less pathologic fat metabolism, with an organism requiring sodium bicarbonate and also abnormal quantities of water in order to dissolve the unoxidized products formed.

It seems passing strange that with all the wealth of modern chemistry no compound is known which will replace dextrose in metabolism.

A final question is whether the heat production is less in diabetes than in health. It can now be positively stated that there is no diminution in the total energy production of the diabetic as compared with the normal man. The diabetic obtains his calorific energy from fat instead of from carbohydrates, and if fat is not given him in sufficient quantity to maintain his requirement he uses his own body fat.

[3] Klein and Moritz: Deutsch. Arch. f. klin. Med., 1910, xcix, 162.

Pettenkofer and Voit in early experiments on a diabetic found no change in the metabolism from the normal. Rubner, using a phlorhizinized dog, found that the heat production was increased by 7 per cent. when glycosuria was induced. The protein metabolism was increased more than threefold, and he attributed the rise in energy production to the increased protein destruction (specific dynamic action of protein). Falta,[4] working with Benedict in Boston, could find no evidence of an increased metabolism in diabetes mellitus. Du Bois and Veeder[5] report a comparison between the metabolism of a normal man and two men suffering from diabetes. One case, which was of the most severe type of diabetes, showed an increase in metabolism of 5 per cent. above the normal. Finally, a preliminary report by F. G. Benedict and E. P. Joslin of work on the metabolism of thirteen patients representing various types of diabetes, declares that the heat production of the diabetic may be 15 per cent. above the normal. Zuntz attributes this rise in metabolism to increased renal activity.

One must take to heart these lessons. The physician can be sure that he is treating his patient properly only when he knows that he is giving him at least the thirty-five calories per kilogram required normally, and these must be contained in materials which the patient can oxidize. Protein will not give more than 10 or 15 per cent. of this requirement of energy. To give fat in sufficient quantity requires all the arts of cookery. Here, as always, when the appetite is no longer a proper guide the physician's knowledge of the patient's requirement is the only possible resource. When instinct fails science must be invoked.

RECENT ADVANCES IN THE TREATMENT OF DIABETES MELLITUS *

GEORGE B. WALLACE, M.D.
NEW YORK

In spite of all the experimental and clinical work on diabetes which has been done in the past years, a specific or etiologic treatment has not been attained. A striking advance has been made in dietetic treatment, however, and, with the clearer and more detailed knowledge of the metabolic derangement present, gained in the past few years, the general principles of dietetic therapy have undergone considerable modification and have been placed on a firmer foundation. Much yet remains unknown or obscure, but in no disease of metabolism can truly scientific dietetic treatment be more successfully carried out than in diabetes. It has been made clear, however, that no routine line of treatment, however sound it may be in principle, can be applied to all cases and that the treatment of one individual case may differ quite markedly from that of another. The future will undoubtedly show a more definite classification into groups or types than is at present possible.

Numerous attempts have been and are still being made to discover a specific for diabetes. Naturally this work centers in the preparation of glandular extracts, and although so far no success has been attained, some of the work may be briefly mentioned.

In 1907 Rennie and Fraser[1] prepared an extract of the islands of Langerhans of the pancreas of a certain genus of fish, the Teleosts. In these pancreas there is a chief island, large enough to be seen macroscopically. Five diabetic patients were treated with the extract and some improvement seemed to follow. The results have not been confirmed nor have additional cases been since reported by these authors. In the following year a paper by Zuelzer[2] appeared in which were reported six cases treated with pancreas extract. The extract was made from dog's pancreas removed during the height of digestion. It was injected intravenously and the glycosuria diminished perceptibly during the two or three succeeding days. A decrease in the acetonuria was also observed. As a result of the injection fever usually occurred. The figures given by Zuelzer are not very convincing, however, and unfortunately the treatment in the hands of others has been disappointing.

Another line of treatment which attracted some attention was introduced by Moore and Abram[3] in 1906. These investigators failed to find prosecretin in the duodenum of diabetics, and on this basis and the assumption that secretin might increase the internal secretion of the pancreas, employed an acid extract of the duodenal mucous membrane (secretin) in the treatment of a few cases of diabetes. Good results were recorded. Their conclusions were shortly afterwards attacked by Bainbridge[4] who found that prosecretin was usually present in diabetics and that the administration of secretin failed to produce any effect on glycosuria. Bainbridge's work has been confirmed by Foster and others in this country.

In 1908 Minkowski[5] again reported the effects of grafting pancreatic tissue in dogs. The graft, if it secures a sufficient blood-supply, grows and functions to such an extent that the animal's own pancreas can be completely removed without the occurrence of diabetes. Here would seem to be a great therapeutic possibility. But in animal experiments the transplantation must be made before diabetes has been induced, otherwise healing will not take place.

The interesting work of Cohnheim[6] may be mentioned here. Cohnheim found that the glycolysis occurring when an extract of muscle was added to sugar was increased if the further addition of an extract of pancreas be made. The extract of pancreas, he assumes, contains a substance of the nature of a hormone. The objection to his work, on the ground of bacterial contamination, seems to have been successfully met, and Hall,[7] repeating his work, has obtained rather striking results. No attempt has been made by these investigators to apply their work to therapeutics, although it might appear to warrant such application.

A relationship between the function of the pancreas and other glands furnishing an internal secretion, especially the adrenals, has recently been demonstrated, and Eppinger, Falta and Rudinger[8] have assumed that the secretions of the thyroid and adrenals are of mutual aid in affecting metabolic processes, while each of these inhibits the pancreatic function and is in turn inhibited by it. On the basis of this assumption, Bruck[9] has suggested that the serum of an animal deprived of its adrenals will have a beneficial effect in diabetes through lessening the adrenal action, which is excessive on account of the removal or diminution of the pancreatic secretion. Such a line of treatment seems absurd. However interesting and important the knowledge of the relationship between the various internal secretions may be, it offers at present no therapeutic application in diabetes.

There has come a tendency in recent years to a less frequent employment of drugs in diabetes therapy. Alcohol is still used to a large extent in the von Noorden clinic and elsewhere, but von Noorden himself has pointed out that amounts larger than 50 c.c. a day are not to be used. Its food value is of no great importance when taken in this quantity, and it is to be recommended chiefly as an aid to digestion, especially of fat. It would seem here that it is as a rule unnecessary, and while there may be some disadvantage in withdrawing it from those who are accustomed to its use, it must be remembered that diabetics seem especially susceptible to its injurious effects on the various organs of the body. It has been shown too that in some cases, at least, the tolerance for sugar is distinctly lessened by a too free use of alcohol. Neubauer[10] has recently recommended alcohol as a means of warding off diabetic coma and reports cases in which the administration of fairly large doses, up to 135 c.c., has given good results. These doses are too large to be used for any length of time with safety, and, in fact, some other observers have failed to obtain any beneficial effects in this direction.

Considerable interest was aroused in this country by Rudisch's[11] paper on the use of atropin in diabetes. Rudisch finds that atropin, when given in fairly large amounts and in conjunction with dietetic treatment, is of great aid in lessening or preventing glycosuria. In the hands of others, however, it has not been so beneficial, and in a series of experiments I have carried out on depancreatized dogs it produced no effect whatever.

Thus it may be seen that little has been accomplished toward an etiologic or specific therapy and to find any actual progress we must turn to dietetic treatment.

There may be first considered here the question of the energy requirement in diabetes. With the great appetite and marked loss in weight and strength so frequently seen in severe cases it is hardly surprising that the taking of large quantities of food should have seemed a necessity. And in spite of the teaching of those having the largest experience, the idea is still somewhat prevalent that diabetics have a much greater energy requirement and accordingly need a much greater supply of food than normal persons. The following out of this idea has undoubtedly led to considerable injury. The experiments of several investigators have shown that an increased energy requirement does not exist in diabetics. Quite recently a series of experiments carried out in accordance with most approved modern methods has been reported by DuBois and Veeder.[12] They show that the energy requirement in diabetes is approximately 34 calories pro kilogram of body weight per day, which is no greater than that in a healthy man. Diets are generally arranged quantitatively, therefore, with the idea of supplying this amount of energy, due allowance being made for the loss through non-utilization of sugar. Over this point a controversy has arisen. Von Noorden[13] states explicitly that the food-supply of a diabetic must at least be equal to that of a healthy man of the same weight and under the same conditions. If less is taken a loss in weight is sure to occur. On the other hand, the opinion is often expressed that severe cases of diabetes may show a lowered level of energy requirement. Kolisch[14] especially has stated that 25 calories pro kilogram weight may lead to an actual increase in body weight, and that in some cases as little as 20 calories may be taken with no loss in weight. He strongly advises the use of a minimum quantity of food, and claims that this offers the best success in the treatment of severe cases.

In practice it is of course out of the question to determine what is the minimal energy requirement for each case, and the work done in this direction serves chiefly in establishing a principle of treatment. The conclusions which may be safely drawn are that high feeding is injurious, that in some cases of severe diabetes the minimal amount of food which will maintain the body weight brings about the best results, and that an amount equal to that required for a healthy man is generally to be recommended. Starvation days and prolonged periods of low diet are not unattended with danger and are to be prescribed only with due consideration of this.

Another subject of importance concerns the quality or class of food comprising the diet. In mild diabetes certain general principles may be laid down for practically all cases. First, the limit of tolerance for sugar is determined. This is done most easily by gradually increasing the daily amount of bread in the test[15] diet until glycosuria reappears. The patient is then placed on a carbohydrate-free diet for at least two weeks. During this time the sugar tolerance will gradually increase and the hyperglycemia, which very frequently persists for some time after the urine is free of sugar, disappears. It is very rarely that acidosis of any dangerous degree occurs during this period. A mixed diet is now given and the new degree of sugar tolerance determined as before. In many cases it will be found that the tolerance approaches the normal; in others it may show only a slight increase, if any. In all cases, however, the subsequent diet should be such that the urine remains sugar-free and there should come at least once in three months a period of carbohydrate-free diet lasting one or two weeks. This treatment may seem quite unnecessary to a patient whose tolerance for sugar has become well-marked, but it should always be enforced.

In severe cases the qualitative arrangement of the diet is of greater importance. It has long been recognized that a glycosuria persisting under a carbohydrate-free diet may be made to disappear if the protein of the food is cut down. Falta, Gigon[16] and others have shown that some patients may have a marked susceptibility to protein; more so, in fact, than to carbohydrate; so that glycosuria may be lessened or at least not increased by cutting down the protein and at the same time adding carbohydrate. The fact is certainly now well established that high protein feeding is not desirable in severe cases. Two hundred grams of cooked meat per day is the maximum allowed by von Noorden and not more than 12 to 15 gm. of nitrogen should appear in the urine. The proteins of eggs and especially of vegetables, are to be preferred to those of meat since they affect the glycosuria less. It is on this account that periods of vegetable feeding are so beneficial.

[15] I employ the standard test diet used in the von Noorden clinic for the determination of the severity of the case. This diet contains 75 grams of white bread. The detailed diet and the method of classifying diabetes into mild and severe forms are described by von Noorden in Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition, E. B. Treat & Co., N. Y., 1905, *part* 7, *p.* 175.

With regard to carbohydrate feeding in severe cases it is well known that most patients do better when one kind of starch is given alone than when several kinds are taken together. This is the basis for the rice, potato and oatmeal treatments. Of these the oatmeal treatment is of greatest importance. The manner of its action is not understood, but the beneficial effects following its use are at times remarkable. All patients are not by any means, however, equally affected. Although it often brings about a decrease in glycosuria and an increase in sugar tolerance, its chief effect is in lessening acidosis. It is to be given alone, i. e., with no other carbohydrate, and in amounts of 250 gm. a day.[17]

Finally with regard to fat feeding, it is known that although the acetone bodies are formed chiefly from fats, their amount is uninfluenced by the amount of fat in the diet unless in enormous quantities. The lower fatty acids in butter should preferably be removed by washing.

Our knowledge concerning acidosis is as yet very incomplete. In a case in which complete sugar intolerance is present, acidosis may be slight. In another with slight glycosuria, the acidosis may be marked. Allard[18] has pointed out that in diabetic dogs the acidosis is not due to a non-utilization of carbohydrate, but probably to a pathologic state of the liver function. It seems established that the condition is not an acidosis in the strict sense, but rather an intoxication due to specific poisons. Of these one at least we know—oxybutyric acid—and we know too that its salts are poisonous. Our efforts in treatment are directed toward preventing the excessive formation of these substances and in hastening their excretion. A strict protein diet increases the acetonuria, but if it can be persisted in an ultimate decrease may often be obtained. So also the addition of carbohydrates to the diet lessens markedly the acidosis, although the glycosuria at once increases. Where coma is threatening, the glycosuria is of course of less importance than the diminution in acidosis. The introduction of periods of vegetable days,[19] and of oatmeal feeding is especially beneficial in persistent acidosis. The action of sodium bicarbonate is chiefly that of increasing the excretion of oxybutyric acid, and one must not be misled by the presence of larger amounts of oxybutyric acid in the urine after its administration. To get the best effects from this salt in severe acidosis it must be given in large amounts, 100 gm. or more a day. Where coma is present it should be given by intravenous injection.

In general the treatment of severe diabetes may be carried out along the following lines. It is as a rule practically impossible to keep the patient's urine sugar-free, and one should early give up the attempt. Since the main danger lies in the acidosis it is unwise to put the patient on a strict diet for any length of time. In the preliminary treatment there comes first a period of strict diet with 75 to 100 gm. of bread; then follows one of a low protein diet, consisting chiefly of vegetables, and finally one consisting of oatmeal. Each of these is of two or three days' duration. By repeating this procedure for two or three weeks there may be obtained a lowering of acidosis to such an extent that it ceases to be an immediate danger, and there may be obtained also a clear conception of the degree of sugar tolerance. The subsequent treatment is based on the results obtained. A carbohydrate-free diet can often be given for a week or so with marked general improvement. The patient is then allowed a small amount of carbohydrate, or a more prolonged oatmeal or vegetable diet may be given. Every few weeks a period of strict protein-fat feeding of two or three days may be ordered, and once or twice a year a longer period, two or three weeks, should be tried. In conclusion it must be emphasized that no general rule can apply to all cases. Each case must be studied individually and only by such study can the proper line of treatment for any particular case be determined.

THE ACTION OF GLYCOL ALDEHYD AND GLYCERIN ALDEHYD IN DIABETES MELLITUS AND THE NATURE OF ANTIKETOGENESIS *

R. T. WOODYATT, M.D.
CHICAGO

It is generally known that the acetone bodies (acetone, aceto-acetic acid and beta-oxybutyric acid) have their origin in butyric acid, which in turn comes from the fats and to a lesser extent from the proteins, and that the main prerequisite for development of acidosis is a diminution in sugar oxidation. When for any reason the daily oxidation of sugar in the body falls below a certain minimum (say 50 to 75 gm. per day for a man weighing 75 kilograms) then some degree of acidosis supervenes. In the acidosis of starvation, in which lowered sugar combustion is the result of a diminished intake of carbohydrate food, the mere administration of sugar serves to stop the accumulation of acetone bodies. In diabetes, in which the lessened oxidation of sugar is due to the inability on the part of the body to attack the glucose molecule, even when present in abundance, the administration of sugar has less effect than in other acidoses. But, though a diabetic cannot oxidize glucose, he may be able to oxidize other substances chemically allied thereto, such as gluconic acid, saccharic acid, alcohol, etc., and thus lower the existing acidosis. Sugars and allied substances which in oxidizing in the body have the power to lower acidosis are known as antiketogenic substances.

---

16. Gigon: München. med. Wchnschr., 1909, lvi, 907.
17. The oatmeal is given as gruel; 200-300 gm. butter is usually taken also, and there may be added a few eggs and vegetables.
18. Allard: Arch. f. exper. Path. u. Pharmakol., 1908, lix, 338.
19. The following vegetables may be used; asparagus, cauliflower, string beans, Brussel sprouts, cabbage, sauerkraut, spinach, lettuce, endives, olives. In addition 4 to 6 eggs are taken daily.

* Read in the joint meeting of the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology, at the Sixty-First Annual Session, held at St. Louis, June, 1910.

• The original incentive to do this work was received in Munich. When working on the oxidation of glycerin in the second medical clinic of the university, some glycerin aldehyd was prepared, which, at the suggestion of Dr. Otto Neubauer, assistant to Prof. F. Müller, was fed to a diabetic patient then under observation. Later development of the work was done in Chicago in the Medical Department of Rush Medical College (Professor Billings).

How do antiketogenic substances in oxidizing so influence the oxidation of butyric acid that acetone bodies do not accumulate in the body fluids? That they do it is generally recognized. How they do it is an open problem. Nor is it unimportant that we know what the mechanism of the reaction is, for there is little doubt that antiketogenesis is but one manifestation of a more general physiologic principle. Cathcart, for example, has recently shown that oxidizing sugars have a modifying influence on certain aspects of protein metabolism. A study of antiketogenesis furthermore holds out a reasonable hope that among the many substances whose chemical formulas indicate that they possess antiketogenic properties there may be some which will not have the injurious by-effects of the antiketogens now known, and which will find a practical application in the clinic. Finally an elucidation of this mechanism should put into our hands a means for illuminating some of the darkness which now covers the subject of the breakdown of glucose in the body. For, if antiketogenesis is an effect due to certain products which occur in the oxidation of glucose, an interaction between these products on the one hand and one or more of the acetone bodies on the other, as seems highly probable, then, *vice versa,* any substance which is antiketogenic has a certain claim to recognition as a possible breakdown product of glucose in the body. If the substance prove relatively non-toxic and completely oxidizable in the body its claim is strengthened; and if in addition to these qualifications it is known to be one of the substances which occur outside the body when glucose is oxidized under such conditions as most closely simulate those of the body, then its qualifications are strong. With these three considerations in view a systematic study of the whole problem was planned along the following general lines:

First, to tabulate those substances which as the result of later chemical investigations appear to be important as intermediate steps in the laboratory oxidation of glucose under such conditions as have been mentioned. In this class belong the oxidations of sugar in alkaline media by means of hydrogen peroxid, or the air stream, as elaborately worked out by Nef and his pupils. Secondly, to prepare, whenever feasible, sufficient quantities of these substances for use in metabolism experiments in cases of severe human diabetes in which the ability to utilize glucose has so far disappeared that any substance passing into that hexose in the body will be almost quantitatively excreted as such, whereas a high acidosis will always exist and by its fluctuations give an index of the combustion of the antiketogen in the body.

EXPERIMENTAL ANTIKETOGENESIS

In this place the purpose is to mention briefly the results of experiments in which two of the substances which belong in the above-mentioned tabulation were employed, and, in addition, to draw attention to what is believed to be a plausible explanation, in purely chemical terms, of the phenomenon of antiketogenesis. This process appears to be the expression of a simultaneous oxidation and reduction reaction in which aceto-acetic acid, by virtue of its ketone group, acts as the oxidizing agent and hence undergoes reduction, while any substance containing alcohol groups, or the dissociation of which yields the same unsaturated molecules as do alcohols, acts as the reducing agent and hence becomes oxidized.

The first substance to be considered is glycol aldehyd or diose, the simplest possible sugar, of which there is only one. Its formula is $CH_2OH\text{-}COH$. This was fed as a single 20-gm. dose to a patient with severe diabetes, a young man who had been under close observation for a period of two weeks prior to the giving of the experimental substance. Daily determinations were made of the body weight, the amount and specific gravity of the urine, the amount of sugar (by polarization and reduction controlled at intervals by fermentation), the combined acetone and aceto-acetic acid, beta-oxybutyric acid, ammonia and total nitrogen. In addition to these figures accurate observations were made on the ether-soluble acids, both volatile and non-volatile. The patient was kept in bed and all necessary precautions taken with regard to diet and the collection of excretions to insure a consistent metabolism experiment. There was no increase in urinary reducing substances, no appearance of glycol aldehyd in the urine, and no significant change in the total acetone bodies or ammonium. The patient, however, experienced some nausea and a loosening of the bowels. In view of the fact that Paul Meyer saw toxic effects when he administered an impure glycol aldehyd to rabbits, and since two of the oxidation products of glycol aldehyd, namely oxalic acid and glyoxal, are toxic, it seemed likely that these gastro-intestinal symptoms were not merely incidental to the existing acidosis. Accordingly no further use was made of this substance in diabetes mellitus. From animal experiments, however, it is evident that glycol aldehyd can pass over into glucose in the body and that in oxidizing it can act as an antiketogenic body. Owing to its toxicity, glycol aldehyd can hardly be looked on as one of the main splitting products of glucose in the body.

When glucose is placed in an alkaline solution there probably occurs, among other changes, a partial splitting into two molecules of glycerin aldehyd. This aldehyd by intramolecular rearrangement is responsible for formation of lactic acid when the solution contains deficient oxygen, or for glycerinic acid and oxidation products thereof when air or peroxid are present beside alkali (Nef[1]). Glycerin aldehyd is therefore, *in vitro,* an important intermediate product in the breakdown of the hexose molecule by such methods as we are here discussing. Since lactic acid occurs in the body and, furthermore, as is well known, under conditions which make for a deficiency of oxygen in the tissues, *e. g.,* epileptic fits, strychnin convulsions and cyanosis, it would seem highly probable that glycerin aldehyd also plays a part in the bodily dissociation of hexose. So far as I know we have no data on the biologic behavior of this substance except an unsupported statement by Neuberg that in the animal body and in the diabetic organism it is completely oxidized, a statement not entirely accurate.

The glycerin aldehyd used in the experiments to be reported was made by oxidizing glycerin with hydrogen peroxid, using ferrous sulphate as a catalytic agent; by a slight modification of the method of Fenton and Jackson.[2] As so prepared, glycerin aldehyd is a syrup having a sweet, pleasant taste. It contains about 2 per cent. of water, traces of free acid and glycerin, possibly also some glycol aldehyd. It rapidly polymerizes in the presence of alkalies, even traces being sufficient. It gives a vivid aldehyd reaction with Schiff's reagent, reduces Fehling's solution at room temperature, and silvers the wall of test-tubes containing ammoniacal silver oxid solution.

When given to a healthy individual large doses are tolerated without any apparent effect. In cases of diabetes in which 20 gm. of glucose caused appearance of sugar in the urine as high as 50 gm. of glycerin aldehyd were given without causing glycosuria, or the appearance

---

1. Nef: Ann. d. Chem. (Liebig's) ccclvii.
2. Fenton and Jackson: Roy. Chem. Soc., lxxv, 4.

of any reducing substance in the urine. But it is to be distinctly stated that continued dosages of this kind have not yet been given, and the results, such as already obtained, are no more striking than were originally obtained and falsely interpreted when levulose was exploited as a sugar which could be used by diabetics. Its effect when given in single large doses to severe diabetic cases has been shown in four separate experiments, all of which yielded essentially the same results. When glycerin aldehyd is administered by mouth in single 50 to 75 gm. doses two things are constantly noticeable if the case is ultra-severe: first, an increase in the urinary glucose in an amount approximately equivalent to 25 per cent. of the total triose administered; second, a marked reduction of acidosis as evidenced by a fall in the figures representing the excretion of acetone, aceto-acetic acid and beta-oxybutyric acids, and by a corresponding fall in the figures for ammonia. The total nitrogen also falls a little, as is to be expected when a sugar oxidizes. Little or no glycerin aldehyd goes into the urine as such. There is a relative increase of the ether-soluble urinary acids. There is never diarrhea, but rather more gastric disturbance than may occur when large doses of an ordinary sugar are given at once. The substance is in moderate doses nontoxic. In dogs and rabbits diarrhea is caused by doses of 3 gm. per kilo of body weight.

There are two ways to explain how glycerin aldehyd passes over into glucose. 1. The glycerin aldehyd may be in part built up in the intestinal wall into an assimilation product of sugar; such a protein compound, perhaps, as Pavy proposes, which later on breaking down yields only glucose regardless of what sugar originally went into its composition. 2. The glycerin aldehyd may be simply polymerized into a hexose in the alkaline media of the intestine (or after absorption therefrom) as it is outside the body in the presence of alkali. Under these conditions it yields beta-acrose. Its further conversion into glucose would then be analogous to that which occurs when any hexose is administered by mouth.

If the latter explanation is correct, then a gradual administration of dilute doses of glycerin aldehyd, which would allow the least chance for accumulation of an excess in the bowel or in the blood, and which would therefore limit the time during which the triose would be exposed to the action of alkali, should avoid condensation and result in more complete oxidation. If the conversion into glucose is an expression of the fact that glycerin aldehyd has been built up into something else by cell action, and that it oxidizes directly only when it is given in such inundating excess that much free glycerin aldehyd passes over into the blood unchanged, then gradual doses should cause greater conversion into glucose, and consequently less oxidation.

A case which had already shown 75 per cent. oxidation of glycerin aldehyd and 25 per cent. excretion as glucose when a single 75-gm. dose of the former had been given showed different effects when the triose was given in small repeated doses. For three consecutive days, 40 gm. per day were administered, the doses being a tablespoonful of a dilute solution every few minutes all day.

The average excretion of glucose for five days prior to the experiment was 68 gm.; for the three days of the experiment the average was 105, a difference of 37 gm.; *i. e.*, about 92 per cent. reappeared in the urine as glucose, and in corroboration of this appearance there was no appreciable reduction in acidosis to indicate that any considerable amount had oxidized. From this striking difference in the behavior of gradual and acute dosages it would seem likely that the conversion of glycerin aldehyd into glucose is the work of a bodily assimilative process which requires time and limited concentration for its fulfilment. However, since single heavy doses of glucose cause a higher percentage of oxidation than gradual ones, the difference might be simply an effect of concentration of sugar in general in the blood. All of these findings support the idea that glycerin aldehyd may well be a normal intermediate product in the bodily oxidation of sugar.

MECHANISM OF ANTIKETOGENESIS

It now remains to be shown what the mechanism of the *reaction* is, whereby sugars and such substances as alcohol, glycerin, glycerin aldehyd, gluconic acid, etc., in the course of their oxidation depress acidosis. As already stated, this is an open problem and one for the solution of which there is no good hypothesis. Nasse's "secondary oxidation" and Naunyn's suggestion that the burning sugar ignites the acetone bodies as a conflagration sets fire to objects in its neighborhood, are really more graphic than chemical. In this communication a suggestion will be made as to the possible nature of this phenomenon, to which Satta gave the name antiketogenesis.

In a long series of contributions to our knowledge of the chemistry of light Ciamician and Silber[3] showed that when ketones, diketones, keto-acids and nitro-bodies are mixed with alcohols (monatomic or polyatomic) and exposed for varying periods to the Italian sunlight, reactions occur in which the alcohols are oxidized and the nitro-bodies, ketones, etc., are reduced. The following serves to illustrate a reaction of this type: In this

$O:C_6H_4\cdot O$	+	CH_3CH_2OH	=	$HO.C_6H_4.OH$	+	$CH_3.COH$
Benzoquinone		Ethyl alcohol		Hydroquinone		Acetaldehyd

instance the two CO or ketone groups of the benzoquinone have each taken up one H atom to give the reduction product hydroquinone, whereas the alcohol group of the ethyl alcohol has lost two H atoms and been converted into the oxidation product, acetaldehyd. One of the substances with which these authors worked was levulinic acid, CH_3-CO-CH_2-CH_2-COOH, which, like aceto-acetic acid contains a CO group—is, in other words, a keto-acid. Levulinic acid when mixed with alcohol and exposed to the sunlight undergoes reductions to the corresponding oxyacid, gamma-oxy-valerianic acid, CH_3-CHOH-CH_2-CH_2-COOH, the alcohol going, as in the above instance, to acetaldehyd. Here then is a chemical reaction capable of fulfilment without the use of strong reagents or extraordinary physical conditions, in which a ketone outside the body may be destroyed by such substances as are known to be "antiketogenic" in the body. And the destruction of the ketone in these instances is simultaneous with oxidation of the alcohol, glycerin or sugar, as the case may be; in fact, the doubly-bound oxygen actually serves as the oxidizing agent.

Now, since aceto-acetic acid, CH_3-CO-CH_2-COOH, like levulinic, a keto-acid, may actually be reduced by means of sodium amalgam to beta-oxybutyric acid, CH_3-CHOH-CH_2-COOH, it would seem likely that aceto-acetic acid would behave with alcohols and sunlight in the same way as the other substances investigated by Ciamician and Silber. As a matter of fact, it has been possible to show that aceto-acetic acid, when mixed with absolute alcohol and long exposed to the action of light, does undergo a reduction to beta-oxybutyric acid, while the alcohol burns to acetaldehyd. Magnus-Levy and others have leaned to the view that aceto-acetic acid, when formed in the body, is destroyed by a direct acid splitting into two molecules of acetic aid, which then oxidize further; whereas, if we assumed that the bodily destruction of aceto-acetic acid produced in accordance with the mechanism of Ciamician and Silber's reaction, we would then have to consider that aceto-acetic acid is destroyed by reduction, not splitting followed by oxidation. Is there any evidence to support such a conception?

As already stated, the Italian writers found that nitro-bodies, like ketones, underwent reduction under the conditions in question. Nitrobenzol, for example, is reduced by alcohol to anilin, according to the general rule. Now, nitrobenzol, when ingested by men or animals, undergoes in the body reduction to para-amino-phenol, a near derivation of anilin and one which occurs in the urine when anilin itself is ingested. Outside the body the reduction depends on simultaneous oxidation of alcohol groups. Is it so dependent in the body? If so, animals in which sugar oxidation is virtually eliminated by the use of phlorhizin and abstinence from food should be unable to reduce nitrobenzol to para-amino-phenol. This appears to be the case. Recently Dakin,[4] Freedmann and Masse Blum[5] have shown that acteto-acetic acid when intravenously injected (as a solution of the sodium salt) into dogs and cats is actually reduced to beta-oxybutyric acid, whereas it is well known that in acidosis very considerable amounts of aceto-acetic acid may be spontaneously introduced into the bloodstream without the appearance of beta-oxybutyric acid in the urine. In favor of the idea that aceto-acetic acid is normally destroyed by reduction in the course of a simultaneous oxidation and reductive reaction like those exploited by Ciamician and Silber, there is the following condensed evidence: Aceto-acetic acid in the presence of an alcohol outside the body is reduced, the alcohol undergoing simultaneous oxidation. Aceto-acetic acid is reduced in the body when sugar (alcohol) oxidation is going on (Dakin et al.). When sugar oxidation fails aceto-acetic acid is spontaneously excreted in large amounts, and moderate amounts of aceto-acetic acid may exist prior to the appearance of any beta-oxybutyric acid in the urine. Nitro-bodies, which act outside the body in the same general way as aceto-acetic acid and other ketones, are also reduced in the healthy body, but when sugar oxidation is eliminated they, too, apparently fail to be reduced. In every case the substances which destroy acidosis in the body also reduce ketones, nitro-bodies, etc., in the sunlight.

Reduction of aceto-acetic acid will account for the disappearance of this substance and its splitting product acetone, *i. e.*, two of the acetone bodies. It must now be asked what becomes of the beta-oxybutyric acid which is formed in the process. There is always the possibility that beta-oxybutyric acid can be oxidized in the body in two different ways. If so, then in health one would conceive of a double oxidation of beta-oxybutyric acid, two products being formed, aceto-acetic acid on the one hand and a dioxybutyric acid on the other. The latter substance. being easily oxidizable, would rapidly burn further. The aceto-acetic acid as fast as formed would be reduced back again into beta-oxybutyric acid. In this way all beta-oxybutyric acid would eventually have to oxidize over the dioxybutyric route, this being the only way in which it could oxidize and stay oxidized.

Note.—One might think here of a sort of organic chemical equilibrium between molecules of, say, beta-oxybutyric acid and those dissociation products thereof whose existence is the prelude to formation of alpha and alpha-beta oxyacids respectively, such equilibrium being comparable to that which exists in a solution of an electrolyte between the molecules of *the electrolyte and its ions as expressed* for NaCl by the familiar formula

$$\frac{Na \times Cl}{NaCl} = K.$$

If the proportionate concentrations of beta particles becomes lessened by a rapid excretion of aceto-acetic acid instead of being maintained by constant reductions of the same the equilibrium would become disturbed and in the attempt to maintain it a very high aggregate amount of beta products would be formed and a very low aggregate of alpha-beta products. Normally the entire balance may be reversed in simple accordance with the laws of mass action.

THE RELATION OF THE PANCREAS TO DIABETES *

JOSEPH H. PRATT, M.D.
BOSTON

Over two hundred years ago Conrad Brunner[1] showed by experiments on dogs that a large portion of the pancreas could be removed without affecting the health of the animals. Progress in the physiology of the pancreas was slow and as late as 1888 the conclusions reached by Martinotti[2] in his experimental studies published that year were those generally accepted. Martinotti asserted that after the complete extirpation of the pancreas no disturbance resulted either in the general condition or in the digestive functions. The dogs in fact gained in weight. Claude Bernard[3] had asserted that shutting off the pancreatic juice by injecting oil into the ducts under considerable pressure, caused a serious disturbance in the absorption of fat, but subsequent investigators were unable to confirm his observations.

The idea that there was some relation between diabetes and disease of the pancreas was entertained by a number of clinicians, including Frerichs,[4] Bouchardat,[5] Lancereaux,[6] Popper,[7] Lapierre,[8] and Baumel,[9] who were impressed with the frequent association of the two conditions. They thought that diabetes was the result of a disturbance in the composition of the pancreatic juice so that it acted abnormally on the sugar-producing foods in the intestine, or that the juice deficient in some particular was absorbed from the intestine and interfered with carbohydrate metabolism in the tissues of the body.

In 1889 von Mering and Minkowski[10] made the important discovery that after complete extirpation of the pancreas in dogs a severe and rapidly fatal diabetes always developed. The secretion of the sugar began usually on the day following the operation, but occasionally within five or six hours. The failure of the earlier experimenters to produce diabetes by extirpation of the pancreas was readily explained, as none of them had succeeded in removing all the pancreatic tissue. Von Mering and Minkowski found that the diabetes developed in dogs that had been kept fasting for a long time and in which the intestines were empty. This showed that the diabetes could not be due to the cessation of some hypothetic action which the pancreatic juice has on the ingested food, for the diabetes developed promptly although there was no food in the intestine. Hence they concluded that extirpation of the pancreas produced some disturbance in the intermediate metabolism. There are two possibilities, they said: 1. There is an accumulation of some substance in the body, possibly a ferment or a poison, which is normally destroyed by the pancreas. After the pancreas has been removed this substance causes the elimination of the sugar. 2. The destruction of sugar in the organism is a normal function of the pancreas.

The experiments of von Mering and Minkowski have been repeated and confirmed by many investigators. The total removal of the pancreas in the dog, cat and other mammals always produces a severe and rapidly fatal diabetes.

At the time of the discovery of pancreatic diabetes little was known of the internal secretion of ductless glands. Brown-Séquard's[11] views on the internal secretion of the testes were not published until 1889. Claude Bernard[12] as early as 1855 had used the expression *sécrétion interne* in describing the glycogenic function of the liver, but that term is not used by von Mering and Minkowski in their first papers. They did conclude, however, that the experimental diabetes produced by removal of the pancreas was due to the cessation of a "specific, hitherto unknown function of the pancreas." Lépine[13] a little later asserted that the pancreas furnished an internal secretion, and he attempted to prove by experiments that this secretion contained a ferment with glycolytic power which passed from the pancreas into the blood, and was taken up by the leukocytes. Lépine supported his theory by the demonstration that the sugar-destroying power of the blood was diminished in experimental pancreatic diabetes as well as in human diabetes. The extirpation of the pancreas removed the chief source of production of this ferment and thereby the glycolytic power of the blood was diminished. This work seemed to furnish strong evidence that the pancreas produced an internal secretion, but his claims were quickly disproved by a number of investigators (Arthus,[14] Kraus,[15] Minkowski[16] and others). It was shown that the glycolysis observed by Lépine was probably due to post-mortem changes in the blood. His methods were called in question and his statement that the glycolysis in normal blood was greater than in diabetic blood could not be verified. Even if Lépine's observations had been correct the ferment content of the blood alone would not have been sufficient to produce the normal destruction of sugar in the body.

Years later when O. Cohnheim's[17] studies appeared it seemed as if the long-sought-for internal secretion of the pancreas was at last discovered. Cohnheim found that a fresh extract of the pancreas does not destroy sugar and that muscle juice has only slight action; but when the two are combined the mixture acquires marked glycolytic power. The substance furnished by the pancreas is not destroyed by heat. It is supposed to activate the ferment of the muscle which then is able to cause the combustion of sugar. The muscle ferment is thermolabile and readily destroyed by any adverse condition. An excess of the pancreatic excitor has an inhibitory action. Cohnheim's observations have been supported by Arnheim and Rosenbaum,[18] Hirsch,[19] De Witt[20] and Hall,[21] but the later studies of Simpson[22] as well as the work of Claus and Embden,[23] have thrown doubts on their value. Vahlen[24] believes that he has obtained a product of the pancreas which produces the vital destruction of sugar in a purely katalytic manner.

Chauveaux and Kaufmann,[25] mindful of the teachings of Claude Bernard,[26] attempted to modify his hepato-neurogenic theory of diabetes to accord with the discovery of pancreatic diabetes. The source of the sugar according to their views is the liver. The normal production of sugar in the liver is under the regulating influence of the nervous system and the pancreas. The nerves passing to the liver carry stimulating impulses, while the pancreas has an inhibitory action on the formation of sugar. Although at first they held to the view that this influence of the pancreas on the sugar-forming function of the liver was through the nervous system, they later, as a result of experimental study, supported the view that the pancreas furnished an internal secretion which was carried by the blood to the liver. When the pancreas is extirpated the inhibitory influences cease. Pancreatic diabetes would thus be the result of an increased production of sugar, and not of diminished destruction. No recent writers have accepted the theory of Chauveaux and Kaufmann.

The theory that the experimental diabetes produced by von Mering and Minkowski is due to lack of the internal secretion of the pancreas has been accepted by most physiologists and pathologists. It has had its opponents, however, chief of whom has been Pflüger.[27]

This investigator contended that the antidiabetic power of the pancreas is under the control of the nervous system, and he actively opposed the theory that the pancreas furnished an internal secretion. He asserted that there was in the wall of the duodenum an "antidiabetic" central organ rich in ganglion cells, which by means of nerves passing to the pancreas governed the antidiabetic power of that gland. Pflüger supported his position by experiments on frogs. After extirpation of a portion of the duodenum in contact with the pancreas the frogs developed as severe a diabetes as was ever observed after total extirpation of the pancreas. If

this view was correct, said Pflüger, then cutting the nerves which pass from the duodenum to the pancreas would produce diabetes with the intestine and pancreas uninjured. As he expected, this simple procedure produced as marked a diabetes as when the pancreas or duodenum was extirpated. Only a few experiments were performed on dogs, but Pflüger asserted that removal of the duodenum produced glycosuria, although he emphasized the difficulty of the operation. The speedy death of the animals rendered his experiments on dogs unsatisfactory. Pflüger concluded on the basis of his experimental work that the pancreatic diabetes of von Mering and Minkowski was really duodenal diabetes, and was due to the destruction of nerves passing from the antidiabetic centers in the duodenum.

Pflüger's study of "duodenal diabetes" and his theory of the nervous origin of diabetes attracted much attention. It was not long before Ehrmann,[28] Lauwens,[29] Rosenberg,[30] and Minkowski[31] showed the error of Pflüger's conclusions, at least so far as dogs and other mammals were concerned. They found that the total removal of the duodenum in the dog was not followed by diabetes.

In six dogs and two cats Dr. Murphy and I have dissected the pancreas free from the duodenum, leaving only a few branches of the pancreatico-duodenal artery and vein connecting the two. In none of the experiments did glycosuria result, although the nerves passing from the duodenum were cut and a new nervous connection was prevented by drawing the omentum between the duodenum and the corpus pancreatis.

Recent publications by Rosenberg[32] and Löwit[33] give satisfactory evidence that "duodenal diabetes" does not exist in frogs. There is then no justification for the use of the term. The glycosuria observed by Pflüger was a *Kaltediabetes* produced by keeping his frogs on ice.

Transplantation experiments support the theory that the pancreas furnishes an internal secretion. Minkowski[34] and later Hédon[35] and Thiroloix[36] drew a portion of the pancreas out of the peritoneal cavity and placed it beneath the skin of the anterior abdominal wall. The remainder of the gland was extirpated, but sugar did not appear in the urine. When the graft of transplanted pancreas was removed severe diabetes developed. Pflüger[37] and Hédon[38] were not convinced that this experiment excluded the nervous origin of diabetes, for the stalk of mesentery which furnished the blood-supply to the transplanted portion of pancreas also conveyed nerves which connected the graft with the central nervous system. Hédon[38] found that in a large series of experiments cutting of this mesenteric pedicle was followed by diabetes except in three animals. Pflüger's explanation of these exceptions is that the nerves were not severed when the pedicle was cut. But, as Minkowski[31] points out, Pflüger brought forward no evidence in support of his statement. There is really no doubt that necrosis of the transplanted glandular tissue, due to an insufficient blood-supply, is the cause of the diabetes that follows section of the vascular pedicle. Lombroso[39] working with Minkowski recently repeated this experiment of Hédon. After the vascular stalk supplying the transplanted piece of gland was cut there was only a slight glycosuria lasting but three days. Removal of the pancreatic graft was followed by a fatal diabetes. Success in this experiment was probably due to a good-sized artery of the skin that had grown into the pancreatic tissue, and which nourished the graft after the former blood-supply was shut off.

An experiment by Martina[40] furnishes equally strong evidence against Pflüger's neurogenic theory of pancreatic diabetes. The method that Payr employed with success in implanting pieces of thyroid into the spleen was used by Martina, who took a portion of the pancreas wholly free from its vessels and nerves and imbedded it into the spleen of a dog. The animal survived the extirpation of the remainder of the gland the unusually long time of three months, although diabetes of no slight intensity developed.

Forschbach[41] effected the union of two animals according to the method devised by Sauerbruck and Heyde for producing parabiosis. The abdominal walls of two animals were united in adjacent flanks and the peritoneal cavities were brought into communication. There was an exchange of blood and lymph, but certainly no transfer of nervous impulses from one dog to the other. It was found that the parabiosis of a depancreatized dog with a normal animal either prevented diabetes or reduced the glycosuria to one of slight degree. The most plausible explanation of this is that the pancreas of the normal dog furnished some substance to the blood which was carried in the circulation to the depancreatized dog and enabled it to assimilate sugar. Probably some of the sugar passed from the depancreatized dog into the blood-stream of the normal animal and was consumed in its tissues, but Forschbach presents experimental evidence that this was not the only cause of the diminished glycosuria in the dog from which the pancreas had been removed.

There is no proof that the pancreas produces an internal secretion, although the theory is more probable than any other that has been advanced. Pflüger deserves credit for showing how little actual evidence has been brought forward in its support, and his criticism has been a stimulus to many investigators. In his last communication on the subject published in 1909 he said:[42]

> I am, indeed, still of the opinion that the internal secretion has not been demonstrated to be the cause of pancreatic diabetes. What is not proved, however, may nevertheless be true. That is my point of view.

The strongest argument against the theory is the failure to cure pancreatic diabetes or to diminish the glycosuria by the injection of pancreatic extracts or by feeding the fresh gland. Hédon has asserted that the internal secretion of the pancreas will remain a hypothesis until it is possible to isolate from the gland a substance, the injection of which will check completely the diabetes of a depancreatized dog. This investigator performed a large series of experiments with aqueous and glycerin extracts of the pancreas. Even with strict attention to asepsis, abscesses formed at the site of injection unless the extract was passed through a porcelain filter. He was unable to diminish by the use of any pancreatic preparation the intensity of the experimental diabetes. He suggested the possibility that the negative results were due to the presence of antagonistic substances in the pancreatic extract which neutralized each other in the organism.

[42] "Ich bin aber allerdings auch heute noch der Ansicht dass die innere Secretion als Ursache des Pankreasdiabetes nicht bewissen ist. Das nicht Bewissen kann aber noch wahr sein. Das ist mein Standpunkt." Pflüger: Arch. f. d. ges. Physiol., 1909, cxxviii, 125.

Many attempts have been made to treat diabetes in man by feeding the fresh pancreas or by administering pancreatic preparations, but without success. Recently Spooner and I[43] fed the fresh gland to a man known to have pancreatic diabetes. This patient had had suppurative pancreatitis in 1903, and at operation a large amount of necrotic pancreatic tissue was removed. Three years later diabetes developed. He ate two or three raw pancreases daily for a month, but the glycosuria was not diminished.

Starling[44] stated that if the internal secretion of the pancreas is of the same nature as the other bodies which he grouped together under the name of hormones, it should be possible to isolate the active principle from the gland and by introducing it into the circulation to influence favorably cases of diabetes due to pancreatic disease.

Zuelzer[45] in 1907 found that he could prevent adrenalin diabetes by the injection of a pancreatic extract. He later[46] reported that he had used this preparation with success in human diabetes. In preparing the active principle he removed the pancreas, which he had previously rendered hyperemic, at the height of digestion. The juice of the gland was expressed and the protein removed with alcohol. An examination of his report of seven cases shows that the diminution of the glycosuria was only transitory, and that the injection produced a severe febrile toxic condition. Forschbach[47] tried the effect of Zuelzer's "hormone" in two cases of diabetes, but owing to the serious symptoms which resulted its use was abandoned. Probably the decrease in the glycosuria was due largely, if not entirely, to the toxic action of the extract, as instances have been observed, both in man and animals, in which the glycosuria diminished in consequence of a febrile infection.

Pflüger[37] pointed out that the living pancreas may possibly supply the circulating blood with an active internal secretion as rapidly as it is formed, so that there is never more than a trace of the secretion present in the gland. If this be so an extract of the pancreas would not be expected to produce any decrease of the glycosuria.

It is necessary to remove four-fifths or more of the pancreas in order to produce diabetes. Sandmeyer[48] found that if the ducts were tied and partial extirpation of the pancreas performed diabetes developed after a time. Gradual degeneration of the gland followed obstruction of the outflow of the external secretion produced by tying the ducts. Even Pflüger[37] admitted that Sandmeyer's work was evidence in favor of the theory that the pancreas plays a part in the production of diabetes, for even small remains of pancreatic tissue prevented the development of glycosuria which first appeared when they were degenerated. According to Pflüger this fact is the only one that favors the theory that the pancreas furnishes an internal secretion. I have found in my experimental study additional evidence of a similar nature. If all the pancreatic juice is excluded from the intestine rapid atrophy of the gland takes place and the limit of assimilation for glucose drops quickly. In one dog it fell from 121 gm. to 65 gm. within three weeks. In two other dogs it dropped to 35 gm. in from two to three months.

Spooner and I found that the limit of assimilation was raised in an animal with atrophy of the pancreas, by feeding the fresh gland. In a dog with the pancreas entirely separated from the duodenum the limit of assimilation was determined at frequent intervals for a year and it was never more than 35 gm. This animal was then given three sheep's pancreases a day for six weeks and the limit of assimilation rose to 80 gm. It continued to rise for a short time after the administration of fresh pancreas was discontinued and the maximum reached was 100 gm.

The most reasonable explanation for this remarkable increase in the animal's ability to assimilate carbohydrates is that the pancreas fed to the dog contained some substance that passed from the digestive tract into the blood and aided in the metabolism of glucose. It certainly supports the theory of the pancreatic origin of diabetes rather than the neurogenic hypothesis.

Evidence gained from histologic study indicates that there is a close connection between lesions of the pancreas and diabetes. The areas described by Langerhans[49] in 1869 and which bear his name have been thought by many investigators to have as their function the production of an internal secretion. This conception of their nature was first put forward by Laguesse[50] in 1893.

The islands of Langerhans are of irregular outline, as De Witt[20] has shown in her reconstruction models. They are composed of solid columns of polygonal cells with round or oval vesicular nuclei and with a very finely granular protoplasm that does not stain well with eosin. Lane[51] has described two types of cells containing granules of different character, both of which differ in chemical nature from the zymogen granules of the cells of the acini. The islands are highly vascular, the veins and capillaries forming a rich plexus of thin-walled bloodvessels (sinusoids) in intimate relation with the epithelial cells. Flint[52] has shown by means of the digestion method that the connective tissue of the islands is characteristically arranged and differs from that of the rest of the lobule. There is a delicate fibrous capsule which often covers only a portion of the island. It is generally held that these structures are not connected with the excretory ducts, but in pathologic conditions communications with the ducts have occasionally been found.

Histologically there is close resemblance between the islands of Langerhans and the parathyroid and others of the ductless glands. It was on the structural peculiarities of the islands that Laguesse based his view that these bodies are concerned solely with the internal secretion of the pancreas.

Lewaschew,[53] Laguesse,[50, 54] and others regard the islands as acini that have undergone temporary alterations, and they hold that they may change back into secreting acini. It was maintained by Lewaschew on the basis of an experimental investigation that stimulation of the pancreas increased the number of islands. Dale[55] and more recently Laguesse[56] claim to have demonstrated that starvation has the same effect. Dale found that injections of secretin exhausted the acini, thereby converting many of them into islands. Opie[57] in a careful study was unable to confirm Lewaschew's observations. Vincent and Thompson[58] have repeated Dale's experiments and agree with his conclusions.

The theory that the islands are under normal conditions anatomically independent of the rest of the pancreas has stronger evidence for its support. The studies of Pearce[59] and Helly[60] show the early differentiation of these structures in the embryo. The observations of Flint,[52] De Witt[20] and Lane[51] do not accord with the *balancement* theory of Laguesse, but favor the view that the islands of Langerhans are independent structures. The evidence from histologic investigations supports the theory that the pancreas produces an internal secretion.

Schaefer[61] in 1895 was the first to suggest that pathologic alterations of the islands of Langerhans might be the cause of diabetes. Ssobolew[62] announced in 1900 that the islands were absent in two diabetic subjects examined by him. Opie[63] in the same year described marked lesions of the islands of Langerhans in diabetes. His admirable papers aroused great interest and gave a new impetus to the histologic study of the pancreas. Excellent critical reviews of the literature of the subject have been published by Sauerbeck[64] in 1904 and Lombroso[39] in 1910. There is quite general agreement as to the pathologic findings, but much dispute as to their interpretation. As a result of the investigations of the past decade it can be definitely stated that pathologic changes in the pancreas occur in the majority of cases of diabetes. Occasionally the lesions are limited to the islands of Langerhans and occasionally to the acini, but usually both are involved in varying degree.

Most investigators of the subject hold one of two views. The "acinar theory," as it may be called, which was advanced by Hansemann[65] in 1894 has among its other supporters Gutmann,[66] Karakascheff,[67] Herxheimer[68] and Schmidt.[69] They believe that the internal secretion is furnished by the acini, and that pancreatic diabetes is due to disease of the acini.

The theory that the islands of Langerhans alone are concerned with the internal secretion of the pancreas, and that diabetes is due to disease of these structures and not of the acini, is held by Ssobolew,[70] Opie[71] Sauerbeck,[64] De Witt,[20] MacCallum,[72] Cecil[73] and others.

From the literature Sauerbeck[64] collected reports of 176 cases of diabetes in which the pancreas had been examined histologically. In fifteen the gland was normal, in six the lesions were confined to the islands, in twenty-seven to the acini. This would indicate that pathologic alterations are more frequently limited to the acini than to the islands, but Cecil,[73] in ninety cases of diabetes in which he examined the pancreas, found the islands affected in every case in which the acini were involved.

Ssobolew,[70] De Witt[20] and Visentini[74] tied the ducts or placed ligatures about the gland in dogs or cats and found that the acini degenerated, but that the islands were left intact. MacCallum[72] separated one of the two branches of the pancreas from the remainder of the gland. At the end of seven months the atrophied portion contained only the remnants of ducts and masses of cells, which he regarded as the islands of Langerhans.

I have found in a series of experiments on dogs and cats that when all the pancreatic juice is excluded from the intestine there is degeneration and destruction of both the acini and the islands, associated with a great and diffuse development of connective tissue. This has been a constant finding and is a striking contrast to the results obtained by other investigators.

Lombroso,[39, 75] for example, 140 days after ligation of the "pancreatic duct" in a dog found that "not only the islands, but many large groups of acini, preserved a completely normal appearance." Zunz and Mayer[76] confirmed these results. Other investigators as cited above found the islands preserved, but *the acini sclerosed or destroyed*.

Failure to occlude permanently all the ducts is the explanation of these findings. In Lombroso's experiments and in those of Zunz and Mayer we have evidence that the pancreas was still producing its external secretion and furnishing it to the intestine, for metabolism experiments conducted on their animals showed that the absorption of fats and proteins was normal. The fact that a part of the gland was functionating explains the preservation of the secreting tissue. Hess[77] was the first to point out an error into which experimenters have stumbled. He discovered that there were usually more than two excretory ducts in the dogs; hence when only two were tied the pancreatic juice entered the intestine through the accessory channel. Even when all the ducts are tied, necrosis may occur and sinuses carry the secretion into the duodenum, as I discovered early in my experimental work.

Before Minkowski performed his skilful operations it was held that total removal of the pancreas was not followed by any symptoms. It is now known that the failure of the early experimenters to produce diabetes was due to the fact that they did not succeed in removing all the pancreatic tissue. So to-day it is generally held that there is no disturbance in the digestion and absorption of food when the pancreatic juice is excluded from the intestine. This belief is based on the work of Lombroso and others who did not succeed in keeping all of the pancreatic secretion out of the intestine. Lamson, Marks, and I[78] showed conclusively in a recent study that if all the pancreatic secretion is excluded there is always a great decrease in the amount of fat and proteins assimilated. There is marked loss in weight and strength and the animals sometimes die of inanition. Our constant results are due to the skill with which the operation of completely separating the pancreas from the duodenum was performed by Dr. F. T. Murphy. It is a more difficult procedure than total extirpation of the pancreas, as is shown by the failures of many experimenters.

In a dog killed two months after the operation the pancreas was shrunken to a hard mass about 3 cm. long which consisted almost entirely of dense connective tissue. The remains of dilated ducts and acini in scattered areas were present, but no islands of Langerhans remained. The dog did not develop diabetes and hence the internal secretion, if produced at all, must have had its origin in the acini. In a cat which died fifty-three days after the ducts were occluded no islands could be demonstrated, but the protoplasm of many of the acinar cells had lost their characteristic staining properties and the cells resembled in appearance those of the islands in a normal gland. The altered acini, rich in vessels and surrounded by connective tissue, might easily have been mistaken for islands of Langerhans if all transitions from normal acini were not present in the same section. In a dog which died between five and six months after the operation the entire gland, except a small portion near the duodenum, was converted into fibrous tissue with acini and islands entirely destroyed. The dog did not develop diabetes, although the bit of pancreatin tissue remaining contained no islands of Langerhans.

These observations seem to be irreconcilable with the island theory. How can its supporters explain the absence of diabetes when all the islands are destroyed?

If the conclusions of Ssobolew, De Witt and MacCallum were correct and the islands remain intact after tying the ducts it would be difficult for the advocates of the island theory to explain the rapid fall in the limit of assimilation for glucose, which within three weeks in one of our experiments[43] was from 125 gm. to 65 gm. Furthermore, as the marked changes described occur in animals without diabetes it is improbable that slight lesions in the acini, islands, and blood-vessels interfere seriously with the internal function of the pancreas. The severe alterations in the islands found in many cases of diabetes are probably of etiologic importance, although they may be secondary to unknown changes in the metabolism. There is no proof that severe lesions in the acini may not be of equal significance. The islands may be anatomically independent of the acini and yet not physiologically independent. No facts have yet been brought forward to make untenable the hypothesis that the acini as well as the islands of Langerhans may under normal or pathologic conditions produce the pancreatic internal secretion. Neither the island theory nor the acinar theory, nor yet the theory that diabetes may be due to lesions in either acini or islands, explains the many cases of diabetes in which no change occurs in the pancreas. As is well known, diabetes in early life is especially severe, yet in 50 per cent. of the cases in individuals under 30 years of age Cecil[73] found the pancreas normal. It is possible that diabetes without lesions of the pancreas is due to functional changes in the organ, but such a conclusion is pure conjecture, and savors of "learned ignorance."

If the views of Cohnheim[17] and Taylor[79] are correct it may be that the cause of the disease in these cases is not in the pancreas, but is due to a loss in the mass of the muscular ferment, or some disturbance in the relation between the pancreatic "activator" or "zymoexcitor" and the muscular ferment. It is probable that the disturbance in metabolism that occurs in pancreatic diabetes is more complex than present-day theories indicate.

SUMMARY

Despite opposing theories and conflicting observations in regard to the relation of the pancreas to diabetes some facts have been definitely ascertained.

The total removal of the pancreas always leads to a fatal diabetes.

Atrophy of the pancreas produced by excluding all the pancreatic juice from the intestine is associated with a marked decrease in the limit of assimilation for sugar.

Transplantation of a portion of the pancreas prevents the development of diabetes when the rest of the gland is extirpated.

Lesions of the islands of Langerhans are found in most cases of diabetes. They are usually associated with changes in the acini.

In the progressive atrophy which follows the occlusion of all the pancreatic ducts in dogs and cats both islands and acini are gradually destroyed.

All the islands may disappear without diabetes resulting.

The conclusion is justified that the pancreas has an internal function concerned with the metabolism of sugar.

The nature of this function, the relation of the islands of Langerhans to the acini, the significance of histologic changes in both structures, these and other problems still await solution.

HAIRY OR BLACK TONGUE *

M. L. HEIDINGSFELD, M.D.
Professor of Dermatology at the University of Cincinnati; Dermatologist to the Cincinnati Hospital, etc.
CINCINNATI, O.

The subject of hairy or black tongue has engrossed a varied degree of attention in dermatologic literature. A comparatively large number of the cases, chiefly from French and English sources, were reported at the time of the discovery and early mention of the affection. Brosin[1] recorded some forty odd cases reported prior to 1888. The next large increment of cases occurred when investigators first took issue in regard to its parasitic or non-parasitic nature, which has remained a more or less unsettled point of contention to the present day. Relatively few cases have been reported in recent years, not so much because the affection is possibly more rare or exceedingly infrequent as because little additional information could be offered regarding its etiology, pathology and treatment. There are scarcely a hundred cases recorded in the literature at the present time, and if the spurious and unauthenticated cases were eliminated the remainder would probably not total much more than half that number. The earliest report of the affection probably emanates from Rayer,[2] who in 1835 described, under the name *discolorations pigmentaires,* several cases of black discoloration of the dorsal surface of the tongue. Eulenberg[3] in 1853 described a black-coated tongue (*eine schwarze Zungenbelag*) in a 2-year-old child affected with diarrhea, which persisted for several months. He first called attention to involvement of the filiform papillæ, a feature more carefully elaborated later by Gubler.[4] St. Germain[5] in 1855 reported some transient cases of short duration in debilitated individuals, under the name *nigrité de la langue.* Raynaud[6] in 1869 independently described several cases as a new affection, and first ascribed to the condition a parasitic cause. He pictured mycelia and spores, unlike any previously described. As soon as Raynaud attributed a parasitic etiology interest in the affection materially increased; Gallois[7] was unable to confirm Raynaud's observations, and Richter[8] states that he had observed the tongue epithelium to develop into thick, black, cylindrical "turf" (*Rasen*) without ever being able to discover Raynaud's fungus. Féréol[9] likewise found no evidence of spores in his case, and stated that their presence in hairy tongue must be of accidental rather than etiologic character. He considered the hypertrophy of the filiform papillæ the essential pathologic feature, and called the affection *l'hypertrophie épithéliale filiforme.* Within a few years Laveau,[10] Lancereaux,[11] and Dessois[12] reported some cases with which they confirmed Raynaud's parasitic etiology. Dessois attempted to confirm the parasitic nature of the affection by inoculation experiments on his own tongue, which, however, proved negative in character. He named the affection *glossophytie.* Rayer reported that not only were inoculation experiments negative, but morphologically similar spores were present on normal tongues. Pellarez,[13] a Spaniard, erroneously regarded the condition as a vegetating growth and Salter[14] ascribed the discoloration to an anomaly of pigmentation. Butlin[15] believed the fungi normally found in the mouth could, under special conditions, impart a black discoloration to the coating of a tongue. Schech[16] described the discoloration under the microscope as light to dark brown and diffusely distributed over the hairs, without being interspersed with sharp, distinct accumulations of pigment or areas free from pigment. The hairs consisted of thickly crowded masses of long, thin epidermic cells, with a marked tendency to bristle and branch at the borders. They set forth the greatly enlarged, cornified and pigmented filiform papillæ. A remarkable feature was the absence of fine granular masses of cocci, bacilli and leptothrix, which are a part of the normal coating of the tongue. Schech found no evidence of fungi in support of Dessois and Sell and was obliged to retract his former expressed views regarding its mycotic character. Brosin[1] regarded the affection as a hypertrophy of the papillæ filiformes, with abnormal pigmentation and keratosis of the affected tissue. This view was supported by Rosenberg,[17] Rydygier,[18] Wollerand,[19] Surmond,[20] and others, and their studies revealed the presence of many forms of micro-organisms of incidental and non-pathogenic significance.

[1] Brosin: Monatsh. f. prakt. Dermat., 1888, vii, No. 1, Ergänzh., p. 5.

Those who have confirmed the parasitic nature of the affection in more recent years are Roth,[21] who found a micro-organism abundantly present in two cases, to which he attributed the discoloration, and called the affection a keratomycosis. Dinkler[22] disclosed the presence of a filiform bacillus, but was unable to cultivate it. Lake[23] detected the presence of round spores. Ciaglinski and Hawelke[24] and Senziak[25] were able to cultivate a black fungus to which they attributed etiologic importance, but only at room—not at body—temperature. Rostowjew[26] describes in his two cases, in addition to the ordinary mouth bacteria, a peculiar cladothrix, the cultures of which were black. Much infectious significance is attributed by Rostowjew to the occurrence of the affection in husband and wife. Gottheil[27] illustrates the spores in his case, which showed only a black discoloration of the tongue, without a coat of hairlike prolongations. Lucet[28] describes the presence of small round or oval double contoured, highly refractive bodies, with hyaline or finely granular contents. They stained with compound solution of iodin and grew luxuriantly on 5 per cent. glucose agar at 37 C. Inoculation experiments on rabbit tongues were negative. Gottheil named the fungus *Saccharomyces linguæ pilosæ.* Gaston and Laselet[29] believed that the cause of the black discoloration was a fungus which they successfully cultivated. Guéguen[30] is the latest observer to attribute this affection to a hitherto undescribed organism, the *Oospora lingualis.* Equally large is the number of present-day observers and investigators, who either ignore or regard as untenable the theory of the parasitic origin of the affection and attribute it to other causes. Levisseur[31] attributed the cause in his case to use of silver nitrate and chromic acid in the treatment of syphilitic plaques. Schnabel[32] and Schourp[33] regard the affection as a common one among syphilitics, dyspeptics and tobacco users. Audry and Dalous[34] and Hallopeau[35] have observed the affection in cases of Darier's disease. Mourek,[36] in his carefully reported and investigated case, states that micro-organisms were found sparingly and gave no evidence of anything of characteristic significance. The bacteriologic investigation was of negative character. He believed the process is a hyperkeratosis and the discoloration the result of contact with food and other extraneous products. The epithelial cells cohered and became mechanically discolored, as in other keratotic affections of the skin. Vollmer[37] states that though the etiology and mode of production is obscure, he is of the opinion that syphilis, mercurialization, strong disinfectants, tobacco, etc., are predisposing factors. He regards the parasitic etiology as untenable.

REPORT OF CASES

CASE 1.—On May 25, 1909, Mr. A. D., aged 85, was referred to my attention for a peculiar discoloration of the tongue, which was the site of severe subjective pain and discomfort. Examination revealed a brownish-black discoloration extending anteriorly from the circumvallate papillæ to within almost one inch of its tip, and one-half inch of the right lateral border. The affected area was irregularly elliptical in outline, situated for the most part on the right side of the tongue, but slightly transgressed the median line at its middle third. The patch was black at its center with borders that gradually faded from brownish-black to yellowish-brown. The remainder of the tongue and the mucous membranes of the mouth were bright red and normal in appearance. Salivation was very marked, and the patient complained severely of intense pain in the tongue, which was also referred to the ears. The patch was thickly covered with a soft, felt-like coating of hair-like processes, which on more careful examination and inspection were found to be inextricably interwoven and matted together. in the manner of "a field of grain laid low by storm and wind" as previously described by Gubler, Raynaud, Stokes and Lake. An abundance of long hairy filaments, some of which measured ¾ of an inch in length, could be readily removed with thumb forceps. The patient, an intelligent German, stated that his personal attention was first directed to his tongue, some two months prior to the time of the examination, by pain and a sense of soreness in the tongue, and the black discoloration was then in evidence in its present unchanged form. No history of its incipiency or probable duration was obtainable.

Biopsy.—On May 28 a biopsy was made for histologic study. Patient was observed daily. The pain became more intense and salivation more marked. On June 3 a marked swelling manifested itself at the left lateral border of the tongue near its middle third and remote from the hairy involvement; the mass, which was deep-seated in origin, was firm and hard in consistence, irregular in outline. The lesion was diagnosed as an epithelioma and the case referred to a surgeon. The subsequent history confirmed this diagnosis. As soon as ulceration took place the patient experienced some sense of relief from his distressing pain. On Feb. 15, 1910, the bed-ridden patient was still alive, although the disease had made great inroads on his previous fairly robust constitution; death eventually took place March 5, 1910. The complicating malignant growth in this case was, without question, a mere coincidence, and has its analogue in a case of a 49-year-old brickmaker, reported by Lediard, who had an epithelioma at the tip of the tongue remote from the pathologic hairy area.

CASE 2.—R. K., aged 19, was first seen in consultation April 6, 1905. Patient stated that three months previously he noted an abnormal sensation in the tongue, resembling the presence of a foreign body on the surface which could not be dislodged. On looking into a mirror he noted for the first time the black discoloration, became alarmed and forthwith brought the condition to the attention of his physician. The examination revealed an intense blackish discoloration of the tongue, with borders imperceptibly fading to brownish-yellow, occupying a triangular area, extending from the circumvallate papillæ anteriorly along the median dorsal surface of the tongue almost to its tip and lateral borders. The same soft felt-like coating of matted hair-like processes was observed as in the previous case, and a specimen was removed and preserved in alcohol for histologic examination. Pain and distress were entirely absent, and there were no subjective symptoms except as already noted. Patient was last observed in Jan. 15, 1910, and during the intervening five years no appreciable change was detected in the clinical appearance of the tongue. Patient persistently refused a biopsy, but readily permitted the removal of large numbers of hairy processes, some of which measured fully ¾ of an inch in length. Syphilis was absent and there was no history of drug-taking, or the use of caustic or astringent applications.

In addition to these two well-defined clinical cases it has been my privilege to observe several cases of less marked character in connection with conditions of general dermatologic interest. The patients were, almost without exception, unaware of or at least indifferent to the manifestations on the part of the tongue, which were revealed merely by process of routine examination, and doubtless would have been dismissed with passing notice had not the unusual interest of the condition been understood. In most cases there was at least a moderate amount of felt-like covering, of hairy growth, in addition to the brownish or blackish discoloration, and hairs from ⅛ to ¼ of an inch could be readily removed and floated in water or alcohol. In some cases there was mere discoloration without an associated hairy growth, as reported by Gottheil, Stokes, Ciaglinski and Hewelke and Sendziak. This discoloration was soft, mushy in character, and could be freely but somewhat incompletely removed by light scraping. The cases occurred for the most part in early syphilitics and were observed in the process of the examination of the tongue for the presence or absence of mucous plaques, or the coated or non-coated state of the tongue in non-syphilitics. All of the cases occurred in males. Most, but not all, of the syphilitics were using at the time astringent and antiseptic mouth lotions. The patches disappeared, however, in some of these cases, in spite of the persistent use of the astringent antiseptic mouth lotions.

One patient, affected with gonorrhea but not with syphilis, was taking sandalwood oil internally, but the patch persisted for some time after the internal administration of the oil was withdrawn. It disappeared entirely after a lapse of several months.

In two cases syphilitic infection was of long standing; one patient had an extensive leucoplakia of the tongue and these areas were free from the yellowish-brown discoloration, which occupied an irregularly oval area near the center, anterior to the circumvallate papillæ. Most, but not all, of the cases occurred in patients who used tobacco immoderately. Dietary indiscretions and gastrointestinal disturbances were in evidence in the majority but not in all of the cases. The patches were evanescent and transient in all the cases, fading or disappearing without treatment and attention, and occasionally relapsing from untoward local or general influences. These cases lacked the clean-cut clinical characteristics of the first two well-defined cases, in which the color was more intense, the hairs longer, more numerous and interwoven, the patches thicker, more fur-like and sharply defined and more persistent and stable in character. I am inclined to believe that several of the cases reported in the literature belong to this second class of—if I may be pardoned the term—spurious or pseudo cases.

Microscopic Examination.—The microscopic appearance of the hairy-like filaments was fairly constant, when compared with each other and with those described in the literature. Specimens from the pseudo—or spurious—cases could not be differentiated microscopically, except for length and thickness, from those of the two well-defined ones. Specimens unstained and stained by various methods were examined; the unstained specimens, for the most part, showed a more regular and better preserved outline The color of the unstained specimens is a diffuse yellowish brown—as already noted by Schech, Mourek, and others

---

[37] Vollmer: Arch. f. Dermat. u. Syph., 1898, xlvi, 13.

The outline is an elongated cylinder, hair like in general appearance The resemblance to a hair is accentuated in many instances by the presence of a zone analogous to the medullary canal In many there are several of these zones of varying color intensity, and on close examination they are found to owe their presence to the fact that a single filament is often composed of two or more closely united shafts These shafts are united the greater part of their entire length, they become separate and distinct from each other a short distance from the distal extremity, imparting a peculiar tuft like appearance, not altogether unlike that observed in a pineapple (Fig 1, A) Occasionally one of the united shafts will become dissociated at some more median point, and impart an appearance not altogether unlike that of the leaf to a stalk of Indian corn (Fig 1, D) The resemblance to Indian corn becomes more marked if there are several lateral dissociations

Lateral deviations have been noted by Schech and other early observers On closer examination under higher magnification the filaments are observed to be composed of thin, non nucleated, stratified, closely superimposed epithelial cells Their cornified, non nucleated character can be confirmed if the filaments are macerated with gentle heat in a solution of potassium hydroxid The individual cells are superimposed in such a way as to produce serrated borders, the serrations are constantly directed downward, producing a peculiar tesselated effect, which can be compared to the scales on the surface of a pineapple This imbricated character has been frequently noted in the literature, it is not marked enough to conjure up the resemblance of a row of inverted funnels as described by Brosin, nor is their order, as he states, ever reversed, so that they partake of the appearance of a harpoon or trident For similar reasons the spike like appearance or resemblance to the head of a wheat stalk described by Mourek, is not to be discerned, surface indentations were not observed to recall the "corncob" effect described by Levisseur The serrations at the border are directed toward the base and away from the rounded and cleft extremities constantly enough to permit a ready differentiation of the distal from the proximal extremity

In well stained specimens the filaments were observed under oil immersion to be thickly studded with masses of cocci which morphologically resembled the common pus germs They were present in exceedingly large numbers, were intracellular and extracellular, and often in such density as to resemble pure cultures of the common staphylococci Larger and more deeply stained cocci and diplococci were interspersed here and there together with bacilli leptothrix, and various forms of organisms commonly found in the mouth In addition to the various stained micro organisms, a few large round, highly refractive, double contoured bodies, some larger, some smaller, often in such proximity as to impart a budding character, were observed here and there in most of the specimens examined They were not numerous enough to assume pathogenic importance, and to all appearances their presence partook of a coincidental character Some unrecognizable fungi and micro organisms were also observed the micrococci, however, predominated greatly over all other forms

Culture Experiments—Culture experiments were attempted in both genuine and spurious cases The affected surfaces were carefully sponged with ether and 5 per cent glucose agar, nutrient agar and blood serum were carefully inoculated with removed filaments and platinum loop inoculations from the affected area Some of the cultures were kept at 38 C , others at room temperature

The cultures uniformly remained sterile or became the seat of innumerable, small, glistening, white, superficial colonies, which morphologically and microscopically resembled in every particular *Staphylococcus albus* No fungus was evident even on prolonged standing in any of the cultures examined

Histology—A biopsy was obtained only in Case 1, and the histologic report with accompanying illustrations, is the first, to my personal knowledge to be recorded for the affection Under low power the filaments when cut vertically and longitudinally to their long axis are observed to reach upward and forward in irregular parallels (Fig 2) Many of the intertwined filaments are cut transversely and obliquely The filaments preserve for themselves a feather like appearance When cut transversely to their long axis their continuity is preserved only a short distance and most of them appear as small, round or oblique fragments The filaments can often be directly traced to their origin from papilla like projections of the stratum corneum The stratum corneum elongations promptly take on a fringe of serrated, more loosely arranged and deeper staining cells, they often coalesce within a short distance of their proximal extremities with one or more adjacent filaments, to form double, triple, or quadruple filaments Acanthosis is another marked pathologic feature The rete and the papillæ are considerably hypertrophied, and there is a very extensive downward prolongation of almost every fourth, fifth or sixth interpapillary process of the rete Malpighii The lower layer of columnar cells is sharply defined, well preserved and in a state of active proliferation The pars papillaris and subjacent tissue, are entirely devoid of any marked pathologic change save a diffused, mild infiltration of inflammatory products the distribution of which is limited almost exclusively to the pars papillaris

One of the most striking pathologic changes, and possibly second in importance only to the filaments, is the formation of papillæ like bodies within the rete Malpighii (Fig 3) They are differentiated from the rete, in which they are situated, by a well defined layer of more deeply stained columnar basal cells Their well defined interpapillary spaces are devoid of fibro connective tissue and filled with epithelial cells of the rete They are further differentiated from normal papillæ by their diminutive type If cut obliquely or on cross section they partake of the appearance of epithelial nests (Fig 4), and it is not unusual to note six to twelve or more of such nests clustered in a circle If cut longitudinally they can be traced directly to the surface to points where the filaments take their origin (Fig 5) Having assumed that these intra epithelium-placed papillæ are the origin of the hairs, I have termed them "epithelial founts"

The stratum corneum is more or less imperfectly preserved In some places it is of normal thickness structure and staining properties and covers a fair extent of surface In places it is almost entirely lacking, and, when present, rises perpendicularly from the surface to form the proximal extremities of the hair like filaments Where it is preserved, it is often covered or partially covered with a thick layer of partially stratified, nucleated epithelial cells Groups of degenerated cells are occasionally observed at the tips of the papillæ or in the epidermis near the papillary border (Fig 6) These cells are often surrounded by a single layer of endothelial cells, their yellowish color, small homogeneous appearance, angular outline, with interspersed darkly stained lymphocytes, indicate that they are blood accumulations Inasmuch as such accumulations have been observed and recorded in the corneous substance of cutaneous horns by Joseph and others, the analogy is plausible These "blood cavities" and the rete papillary border occasionally contain large rounded hyaline or faintly granular, double culture bodies, which are apparently cell degenerations, rather than pathogenic spores, although they bear a morphologic resemblance to spores to which pathogenic importance has been attributed (Fig 7) They are often embedded in a mass of large, edematous, vacuolated cells situated at the papillary border of the epidermis, which resemble the degenerative cell changes in Paget's disease

The pathology cannot be dismissed without a brief comparative reference to cutaneous horns, ichthyosis hystrix, leptothrix and hair The histopathologic similarity which some of these affections bear to hairy tongue is remarkable to the degree with which their clinical characteristics are dissimilar, and *vice versa,* the affections which preserve the greatest degree of clinical resemblance show the least histopathologic resemblance. Cutaneous horns, which have clinically little or nothing in common with hairy tongue, have much in common pathologically They are composed of masses of cornified, or at least partially stratified, epithelial cells, arranged with wonderful cohesion into dense elongated columns, row after row separated by valley-like clefts, resembling the medullated canals of hair. Intra-epithelial spaces containing blood are also observed. The origin is purely epidermal, and the base rests on and apparently is developed from intra-epithelially placed papillæ and interpapillary processes resting above the area of the true papillæ, and true interpapillary processes, unless the latter, have disappeared from pressure atrophy. The former papillæ and inter-papillary processes correspond to the intra-epithelially placed "epithelial founts" of hairy tongue.

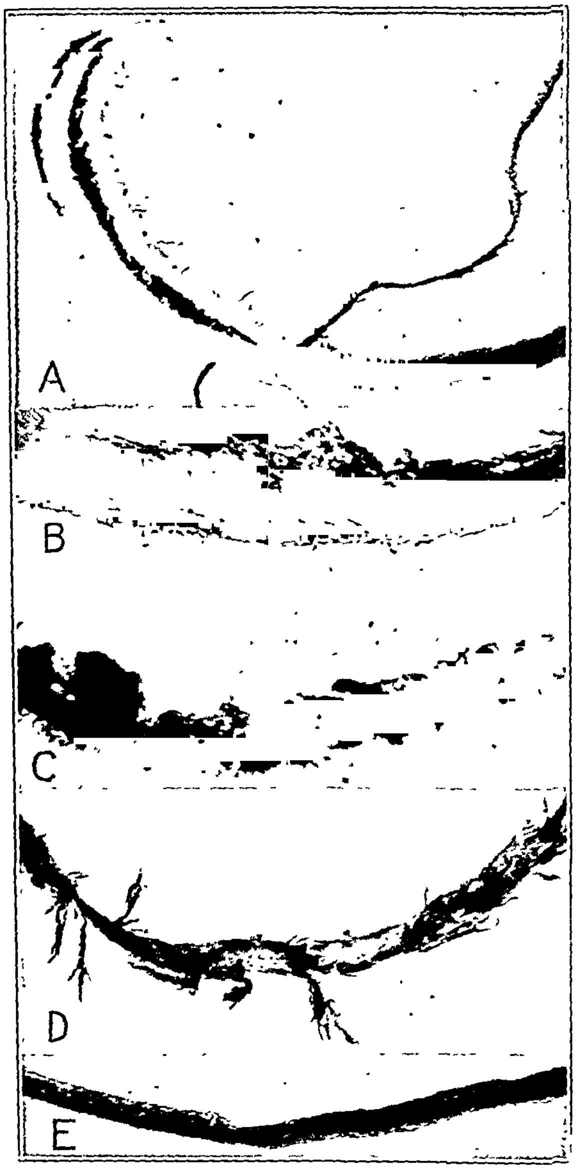

Fig. 1.—Specimens from patient with hairy or black tongue: A, separated from each other at the extremity; appearance, tuft-like; a single hair composed of several closely united shafts; B, stained hair of considerable size; C, unstained filament coated with loose masses, composed largely of micro-organisms; D, hair resembling in appearance a stalk of Indian corn; E, one-half of hair measuring ¾ inch; tenfold magnification.

Ichthyosis hystrix, which preserves possibly more clinical than histopathologic resemblance to hairy tongue, preserves little histologic similarity except a marked hyperkeratosis. The hyperkeratosis, however, is arranged parallel rather than perpendicular to the surface and the spinous processes are the result of keratotic accumulations, spread irregularly over the surface of four or five hypertrophied papillæ. The inflammatory exudate is more perivascular, less diffused in character and more circumscribed to the capillary vessels of the pars papillaris.

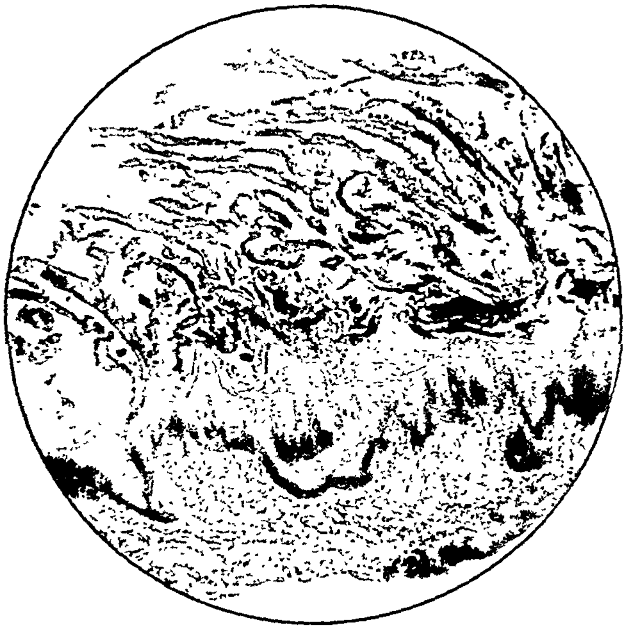

Fig. 2.—Hair-like filaments cut vertically and longitudinally to their long axis. Many intertwined filaments cut obliquely and transversely. Filaments reach upward and forward in irregular parallels.

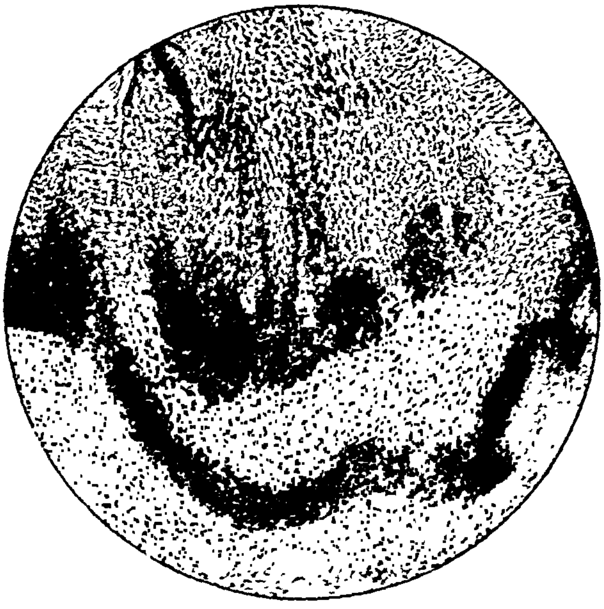

Fig. 3.—Papilla-like bodies within the rete Malpighii; probable origin of hair-like filaments.

Leptothrix, which has little or nothing clinically in common with hairy tongue, shows a striking resemblance under the microscope, in that the affected hairs are coated with an accumulation of loosely adherent cells and detritus, containing myriads of micrococci and other micro-organisms. The morphologic resemblance, under the microscope, of hair affected with leptothrix to the filaments of hairy tongue is very striking. An additional point of resemblance is the discoloration, which in leptothrix is often yellow or red, and in hairy tongue, black to brownish-yellow. Pathogenically there can be little in common in the two affections. The *gross* clinical resemblance which filaments bear to hair is striking enough and gives the affection a misnomer. Remarkable in many of its microscopic features, the resemblance is microscopically and histopathogenically a paradox that requires no comment. In origin, development, essentials of structure and pathogenesis they naturally share nothing in common with hair.

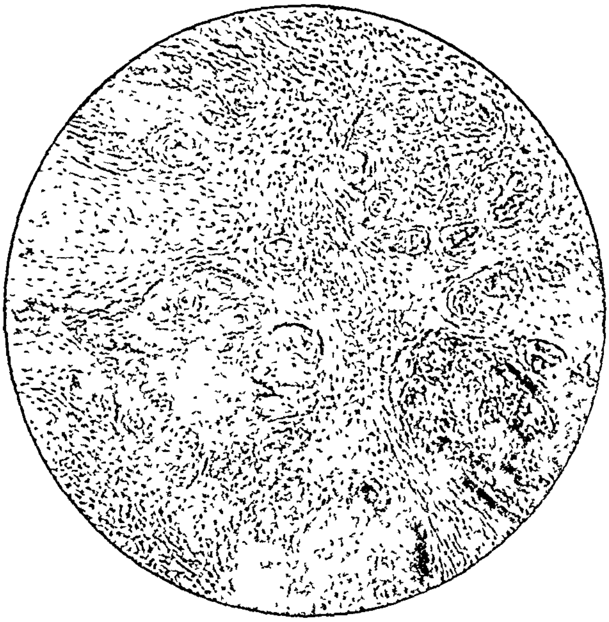

Fig. 4.—The same papilla-like bodies cut transversely and imparting the appearance of epithelial nests clustered in circles.

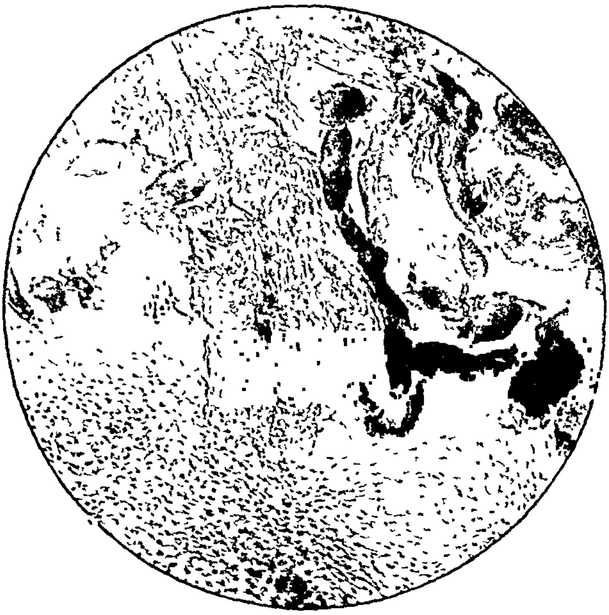

Fig. 5.—Superficial origin of the hair-like filaments.

GENERAL DEDUCTIONS

Hairy tongue can be conveniently divided into two general classes: (1) true, idiopathic, or genuine cases, characterized by well-defined stable, black-brown or yellow-brown, thick, soft, fur-like patches covered with densely intertwined hair-like filaments, easily measuring from ¼ to ½ inches in length; and (2) false, pseudo or spurious cases, characterized by thickish, yellow-brown or greenish discolorations, of unstable evanescent character, covered with a soft mushy detritus, occasionally containing short filaments measuring ⅛ to ¼ of an inch in length. The true cases owe their origin to some anomaly of development, probably of congenital nature, in the sense that the germinal products from which they are developed are present from birth, but do not undergo growth and developmental changes until early adolescence or some later period in life. Such an

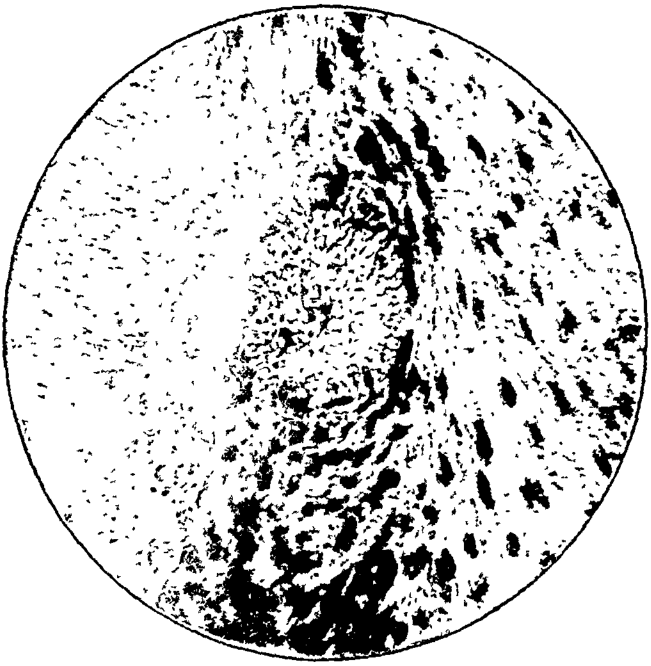

Fig. 6.—Blood cavity strongly magnified, showing its intra-epithelial position. Cavity is lined with a layer of endothelial cells.

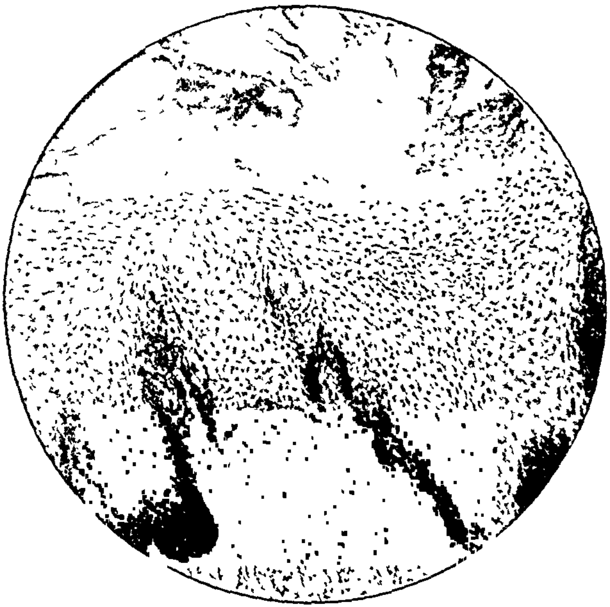

Fig. 7.—Small blood cavity within the epidermis with areas of edematous and degenerated epithelial cells at the rete papillary border.

origin is assumed and very generally conceded for moles, vascular, pigmented papillomatous and unilateral nevi. cutaneous horns,[38] etc., and can be extended with equal propriety to this affection, all the more since the histopathology reveals an anomaly of development (whose striking similarity to cutaneous horns has already been alluded to) rather than any evidence of an infectious or inflammatory nature. An anomalous development and congenital origin is further evidenced by the fact that the true, idiopathic or genuine cases are of stable character, and remain unchanged in size and form for indefinite periods, and localized to definite areas. Such would not likely be the case if they were of infectious origin or of inflammatory character resulting from local or general causes.

The pseudo or spurious cases are unstable and evanescent and probably owe their origin to such local or general irritating and infectious causes as tobacco, antiseptics, astringents, syphilis, etc. The presence of the filaments is probably due to an inflammatory hypertrophy of the papillæ filiformes. These cases in varying degree of intensity can be frequently noted, particularly in the early stages of syphilis, and constitute no uncommon affection. The diagnosis can be easily confirmed by removing some of the grumous coating of discolored tongues by means of fine forceps, and floating it in clear water or alcohol. The hair-like filaments can then be readily seen with the naked eye. The majority of cases recorded in literature probably belong to this group. A parasitic origin for the affection could not be established on either clinical, histopathologic or bacteriologic grounds; it does not develop or spread clinically like a parasitic affection. Inoculation experiments were negative in the sense that the affections could not be distributed to other unaffected parts of the tongue. It failed to spread to the abrasions and excoriations of an intercurrent cancer of the tongue. The histopathology reveals chiefly anomalous structural changes, and the absence of the marked inflammatory changes generally incident to chronic and acute infectious and localized irritations. The fundamental abnormality is the presence of abnormal papillæ, and interpapillary processes or "filament founts" situated within the epidermis, from which the abnormally elongated, stratified and keratosed filaments trace their direct origin. Some of the basal cells at the papillary-rete border showed vacuolated and edematous change, to which, however, no special significance could be attributed. The filaments were freely studded with micro-organisms which resembled *Staphylococcus albus* morphologically, to which likewise no special significance could be attached. A few double-contoured bodies were occasionally observed among the filaments and in the deeper structures, to which no important significance was attributed. The bacteriologic findings were, as already stated, sufficiently negative in character to preclude, in my opinion, a parasitic etiology for the affection.

Ocular Chancre.—Chancres of the eyelids may be palpebral or conjunctival. A chancre situated on the ciliary border of the eyelid may be mistaken for a stye. Conjunctival chancre is more often situated on the palpebral than on the ocular conjunctiva, and generally causes conjunctivitis, chemosis, and eversion of the eyelid. Chancres situated at the outer angle of the eye cause enlargement of the preauricular gland; chancres of the inner angle of the eye cause enlargement of the submaxillary glands.—C. F. Marshall, in the *Practitioner*.

THE COMPARATIVE PATHOLOGY OF HYPERPLASTIC AND SUPPURATIVE ETHMOIDITIS *

ROSS HALL SKILLERN, M.D.
PHILADELPHIA

Last year, when the subject of hyperplastic ethmoiditis, in contradistinction to the suppurative type, was presented before one of our laryngologic societies, the question was raised as to whether these conditions were not

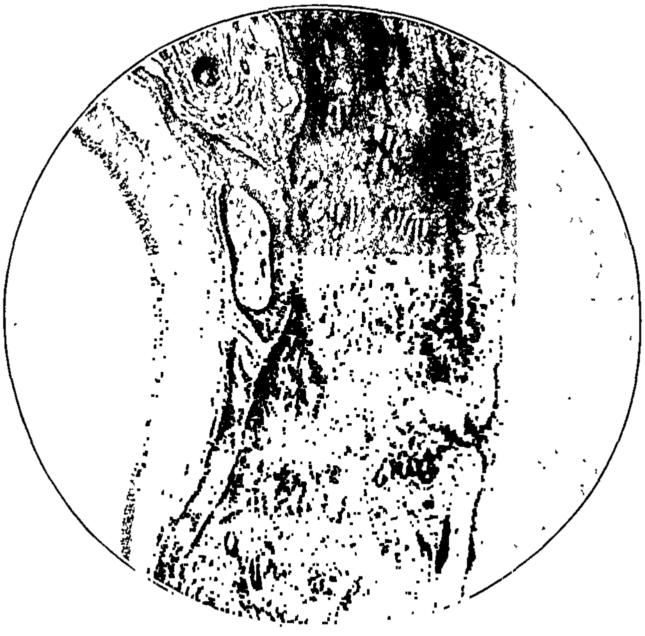

Fig. 1.—Chronic hyperplastic ethmoiditis; processus uncinatus, early stage; beginning polypoid hypertrophy on free border which forms portion of hiatus semilunaris; internal or nasal portion not yet affected.

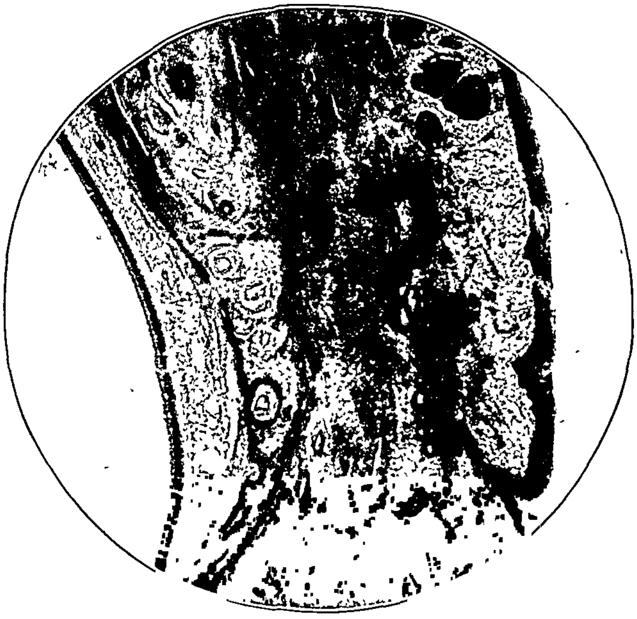

Fig. 2.—Chronic hyperplastic ethmoiditis, later stage. Considerable round-cell infiltration through the polypoid hypertrophy; great infiltration around the glands and blood vessels; medullary spaces infiltrated.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

* From the McManes Laboratory of Pathology, University of Pennsylvania.

identical, or that one was merely a sequela or a complication of the other, as the case might be. It is my intention to bring before you to-day the microscopic pathology of these two conditions and show that the ethmoidal structures and their components are, under certain conditions, dissimilarly affected, and, indeed, often in diametrically opposite ways pathologically. Unfortunately for the argument of our contentions these two conditions can and often do occur simultaneously; i. e., a chronic hyperplastic ethmoiditis may become infected, thus giving us the picture of suppurative ethmoiditis with polyposis. The old question as to the precedence of the polyps of the secretion is, of course, clear in these cases. That the polyp formation in hyperplastic ethmoiditis may occur entirely dissociated from any purulent secretion, past or present, can only be substantiated by the veracity of the patients who have come under observation presenting this form of disease.

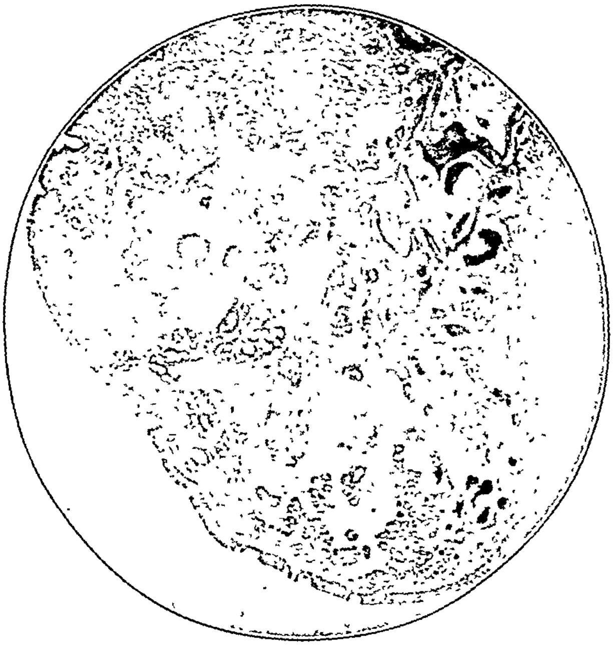

Fig. 3.—Chronic hyperplastic ethmoiditis (end of middle turbinate). Beginning polypoid hypertrophy at extreme end; round-cell infiltration practically absent; ciliated epithelium not affected.

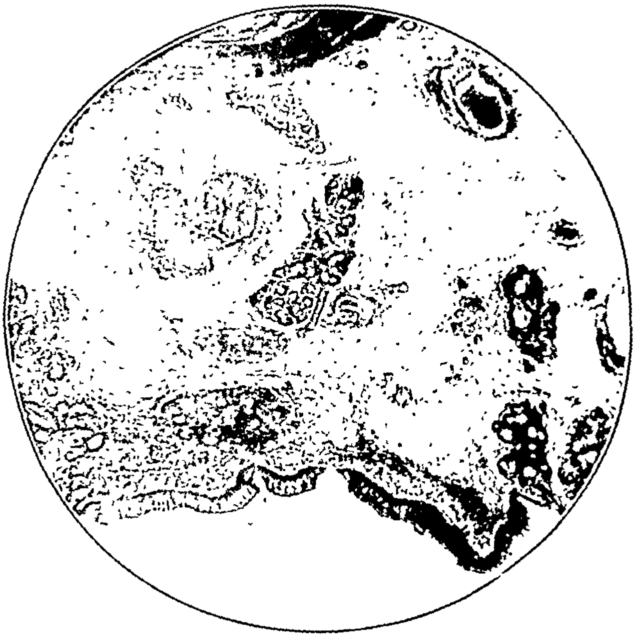

Fig. 4.—Chronic hyperplastic ethmoiditis (base of ethmoidal capsule). Advanced changes; intense round-cell infiltration in basement layers and around glands and blood vessels; periosteum also affected.

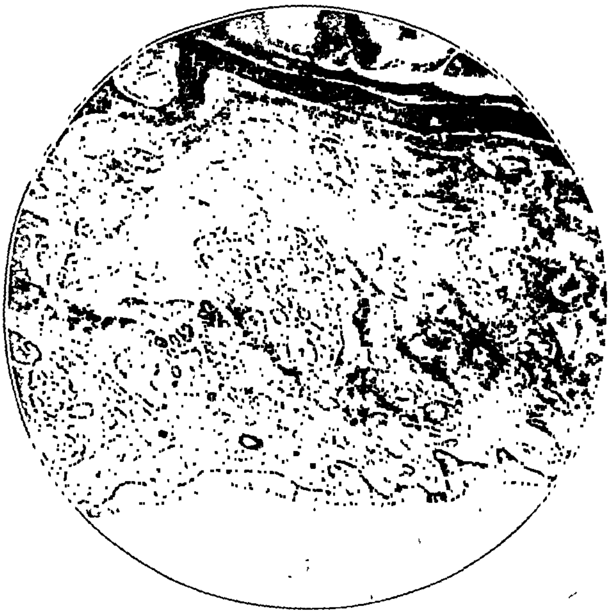

Fig. 5.—Chronic suppurative ethmoiditis (base of ethmoidal capsule). Advanced changes; intense fibrous tissue formation extending from periosteum outward enclosing vessels and glands and reaching almost to basement membrane; moderate round-cell infiltration in outer layers; beginning atrophy of glands.

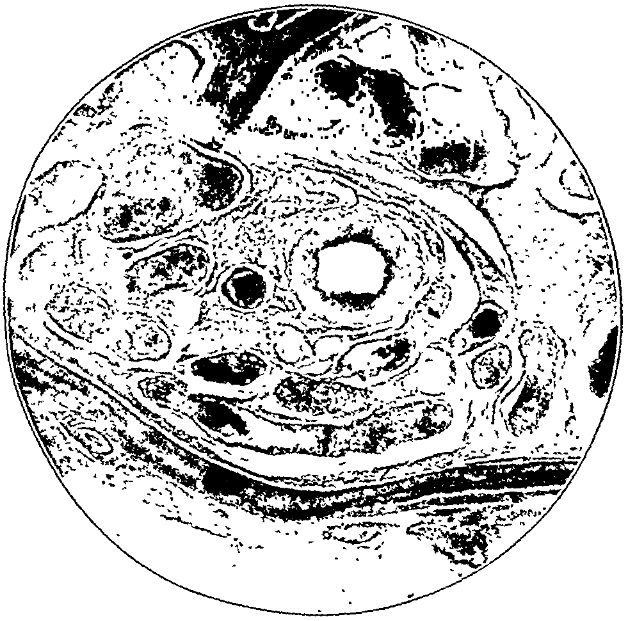

Fig. 6.—Chronic hyperplastic ethmoiditis (medullary spaces, base of ethmoid), hyperemia of entire contents of medullary spaces; proliferation of endosteum; veins distended with blood; lymphatic vessels distended; fibrous tissue formation around arteries.

The discussion as to the relation of polyp formation to empyema, particularly that of precedence, can only be referred to at this place; however, we have all seen empyemas without a vestige of polyp formation, and, on the other hand, polyps springing from the ethmoid region with no traces of pus. The latter class is the one to which objections seem to have been raised as to the presence of previous suppuration, and on this point we must of necessity rely on the veracity and understanding of our patients.

Briefly reviewing the macroscopic pathology of hyperplastic ethmoiditis, it may be defined as a polypoid inflammation of both the lining and external mucous membrane of the ethmoid cells, which may or may not present free polyps hanging from the ethmoid capsule. It is primarily never associated with a purulent secretion, but rather one of a thin, watery consistency, its profuseness being in direct relation to the severity of the disease (area of tissue involved).

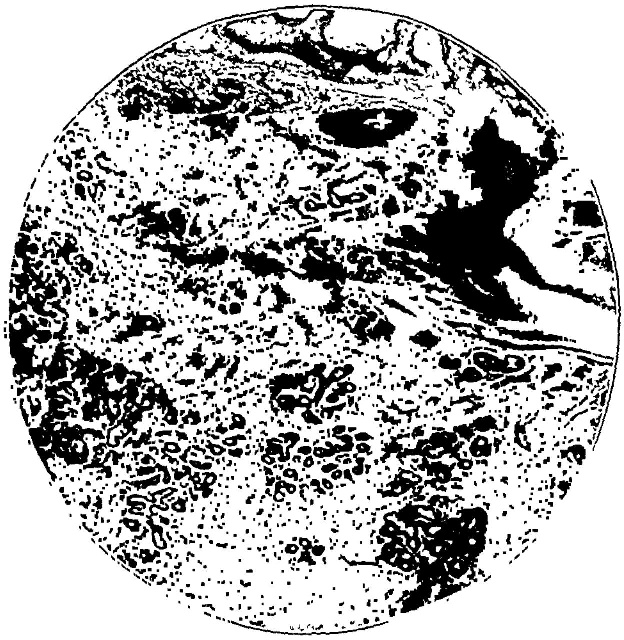

Fig 7.—Chronic suppurative ethmoiditis. Changes in submucous tissue; considerable round-cell infiltration; marked atrophy of glands; beginning fibrous tissue formation.

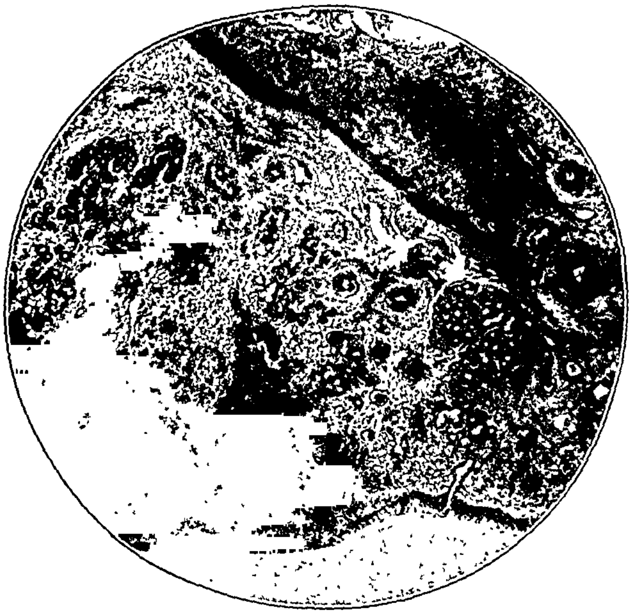

Fig. 9.—Chronic suppurative ethmoiditis. Marked fibrous tissue formation with obliteration of vessels and glands; apposition of new bone formation clearly marked around old bone.

Empyema of the ethmoid cells is characterized by a more or less profuse, constant, purulent secretion, often accompanied by crust formation.

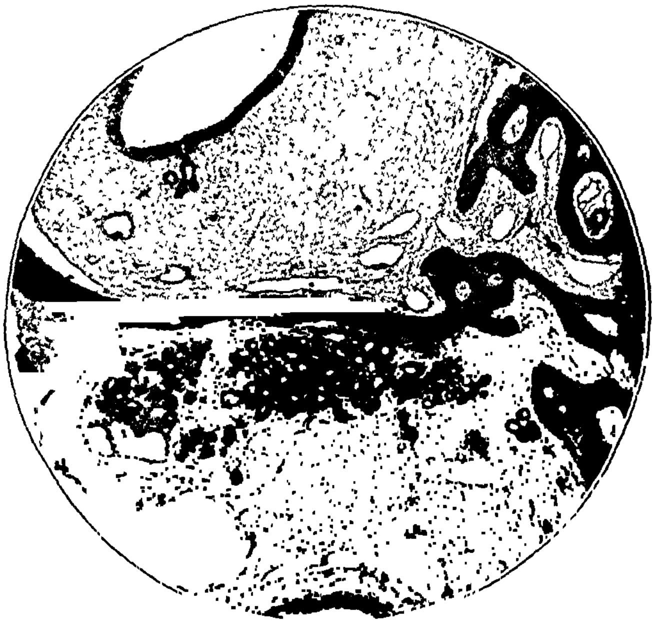

Fig. 8.—Chronic hyperplastic ethmoiditis. Polypoid formation in two separate and distinct cells; beginning atrophy of glands in one cell; blood vessels dilated but empty; medullary spaces and bone apparently normal.

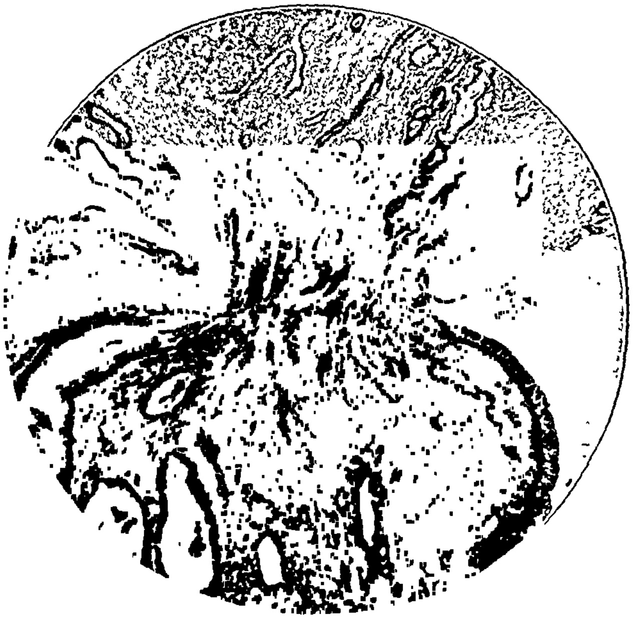

Fig. 10.—Chronic hyperplastic ethmoiditis with secondary empyema. Constriction of a polyp at its neck: below constriction round-cell infiltration and polypoid hypertrophy, glands dilated, blood-vessels obliterated; ciliated epithelium unchanged. Above constriction, fibrous tissue formation, glands atrophied; metamorphosis of ciliated epithelium into squamous

There is no question that many cases of chronic empyema occur without a vestige of polyp formation, and *vice versa*. One can go still further and state that typical empyema of the ethmoid labyrinth runs its course without polyp formation and that simple hyperplastic inflammation runs its course without the formation of purulent secretion. There then remains the combined process, polyp formation with empyema. According to

Uffenorde the formation of purulent secretion is the result of secondary infection and should be viewed as such, being accessory to the hyperplastic condition. The microscopic differences are not so clearly marked, although certain individual peculiarities may always be noted.

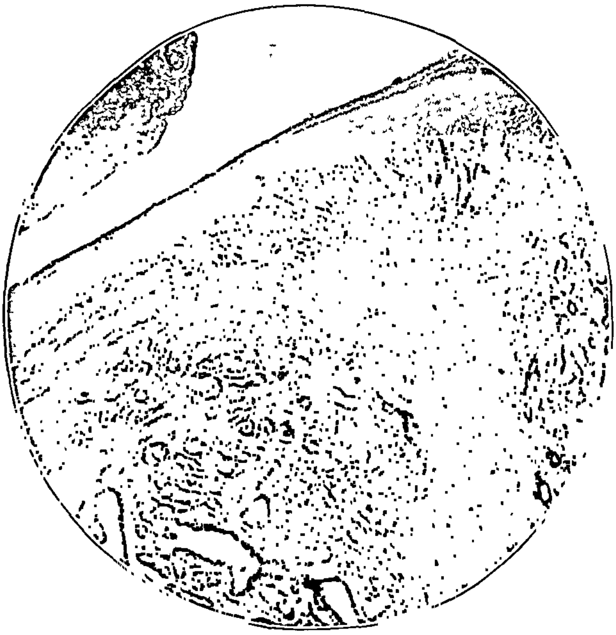

Fig. 11.—Chronic hyperplastic ethmoiditis with secondary empyema. Base of polyp, intense fibrous tissue formation; glands and vessels atrophied; peculiar new bone formation forming fingerlike projections from the old bone.

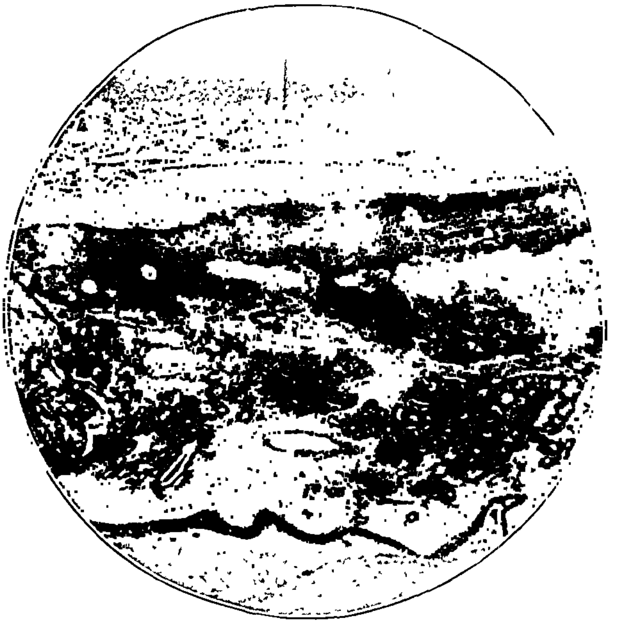

Fig. 12.—Chronic hyperplastic ethmoiditis. Advanced bone changes, marked osteoporosis or erosion of bone in conjunction with previously mentioned advanced changes in surrounding tissues.

These pictures are naturally not absolutely complete, as it requires a large number of microscopic fields to demonstrate every condition which is present in these affections. Combination processes have been omitted (with the exception of Nos. 10 and 11), as they would only tend to cause confusion among the few fields reproduced. The main purpose of this demonstration has been to prove that chronic hyperplastic ethmoiditis and chronic suppurative ethmoiditis are, at least primarily, two separate and distinct pathologic processes.

DIFFERENTIAL DIAGNOSIS

CHRONIC HYPERPLASTIC ETHMOIDITIS	CHRONIC PURULENT ETHMOIDITIS
Secretion clear and watery	Secretion purulent.
Inferior turbinate hypertrophied.	Inferior turbinate atrophied.
Never crust formation.	Always crust formation.
Headache most prominent symptom.	Headache often light or absent.
Ophthalmic manifestations due to pressure of hypertrophic mucous membrane on vessels.	Ophthalmic manifestations due to infection from purulent secretion.
Gastric disturbances absent	Gastric disturbances frequent.
Neurasthenic symptoms predominate	Neurasthenic symptoms not marked if flow of secretion be free.
HYPERPLASTIC TYPE	**SUPPURATIVE TYPE**
Metaplasia of ciliated epithelium into squamous only where parts have come into contact with other structures	General metaplasia where secretion comes into contact with mucosa
Meshes of subepithelial connective tissue dilated.	Subepithelial connective tissue shows fibrous formation.
Round cell infiltration scanty	Round-cell infiltration well marked.
Glands hypertrophied primarily.	Glands primarily atrophied.
Reabsorptive changes in bone predominate.	Apposition of bone predominates.

2032 Chestnut Street.

ABSTRACT OF DISCUSSION

Dr. W. E. Casselberry, Chicago: The research and deductions embodied in this excellent paper explain histologically familiar clinical observations, but do not account for certain of the variations in both types of ethmoiditis with which we are impressed in our operations. Non-suppurative or *hyperplastic ethmoiditis, which followed exactly the course* described by the essayist, I have watched develop and progress in the same patient at periods separated by an interval of ten years. At first there was hypertrophy of both middle and inferior turbinates, the only symptom at that time being nasal stenosis. At the second period, when he applied again for treatment, he was complaining of a sense of pressure far back between the eyes, of a watery nasal discharge, certain neurasthenic symptoms, and it was evident that the bridge of the nose had broadened, which is an important indication of ethmoidal disease. The inferior turbinates were still simply hypertrophied, but the middle turbinates were hypertrophied and polypoid. No real polyps were visible until the middle turbinate was removed, when a flattish polyp was exposed which had been hidden by the turbinate. Doubtless the disease was ethmoiditis from the beginning, but can the deduction be drawn that all cases of hypertrophic rhinitis are to be ascribed in origin to ethmoidal disease? I do not think so, but would value the essayist's full meaning in this respect.

A few years ago, before this Section, I presented a series of illustrations pertaining to atrophic ethmo-rhinitis, so named because I believed that many cases of atrophic rhinitis originated as a suppurative process in the ethmoid bone. Atrophy limited to the inferior turbinal, while the middle turbinal was considerably swollen, had a glistening aspect, and was filmed over by a viscid odorous secretion, represented the first degree. In the second degree, the atrophic process had caused some shrinkage of the enlarged middle turbinal, as shown by lessened breadth and a concave absorption of its under surface, which exposed to view the underlying bulla cell leading to a false bifid aspect. In the third degree, atrophy of the middle turbinals was complete, drainage from the ethmoid cells was thus promoted and Nature's belated amelioration manifest It is a suppurative ethmoiditis, but it differs from the ordinary focal suppuration of one or more cells or sinuses In atrophic ethmo rhinitis I have often curetted up into these cells but did not find one or two cells with a *focus of "laudable" pus but found there the same* character of secretion as in the middle turbinate region, a thick glairy, sticky, semi purulent secretion Evidently there is more than one type of suppurative ethmoiditis, I should like to hear Dr Skillern explain the histologic distinction

Dr George Paull Marquis, Chicago I want to emphasize what the essayist has brought out here as *to* a separate form of ethmoiditis, and I think he has shown, from a pathologic standpoint, what some of us have been observing from a clinical standpoint, that there is a form of ethmoiditis which exists without suppuration Those who claim that this is simply a manifestation of a chronic suppurative ethmoiditis and that there are periods of quiescence and then an exacerbation with suppuration, lose sight of the fact that in such a case during these periods of remission the symptoms absolutely vanish the patient is apparently well' In the hyperplastic form we may have an acute mixed infection giving a clinical picture of suppurative ethmoiditis but as soon as the mixed infection has subsided the symptoms of hyperplastic ethmoiditis continue with watery discharge from the nose, etc The headache accompanying this trouble is probably more severe than in any other form of sinus infection I want to relate a case, that of a clergyman who had had this headache for twenty two years He had had any number of examinations and was told that there was no involvement of the sinuses He had gone to a skillful surgeon and had the supraorbital nerve resected I diagnosed the condition as a hyperplastic ethmoiditis and on opening the ethmoid I removed probably a teaspoonful of granulation mass from this ethmoid that gave no indication in the nose except one which I am going to call to your attention Following that there has been no headache and that is a period now of about eight months This is a typical case in which there was no suppuration in the nose, no polypi, no indication whatever of ethmoidal disease so far as one could observe from our previous methods of diagnosis What then is the diagnostic sign? I would simply refer you to the remarks of Uffenorde, in which he lays stress on the soft, edematous condition of the mucous membrane on the outer wall of the middle turbinate Since studying some time with Uffenorde last year, I *have been on the lookout for these cases and have* been able to find a number I would lay stress on these signs severe headache, supraorbital in character, watery discharge, and so called weakness of the eyes There may be no sign of pus in the nose, no polypi, and not until we *open* the ethmoid do we find the seat of the trouble

Dr O T Freer, Chicago It is only of late that the term ethmoiditis has come into use in the literature, and in a manner which seems based on ill defined pathologic ideas Taken literally, it would mean a total inflammation of an ethmoid bone with its coverings In its present loose employment, however, the designation ethmoiditis is being applied to all chronic inflammations of the ethmoid region, from superficial chronic proliferative catarrhal inflammation limited to the mucous membrane over the middle turbinated bodies, to an inflammatory degeneration of the ethmoidal turbinated bones and the entire ethmoid labyrinth to the orbit In fact, everything which in earlier days was defined as nasal mucous polypi is now classed as ethmoiditis, with the wish to convey the idea that these outgrowths are now known to be merely symptomatic of an invariably grave degeneration of the ethmoid bone and its appendages, a condition demanding a radical extirpation of the ethmoidal cells This view, which I have repeatedly heard expressed, seems to be extreme, and one which has often led to an extensive removal of the ethmoidal turbinated bodies and cells when these structures were quite sound and the true condition merely a polypoid degeneration of the mucous *mem*brane of the middle turbinated body and unciform process I have often seen a complete cure in such cases after merely a thorough clearing away of the polypi that is, not merely with the snare, but with the punch forceps

I think ethmoiditis might be classified as follows 1. Superficial hyperplastic ethmoiditis This type is the most frequent Its main feature is polypoid hyperplasia of the mucous membrane over the middle turbinated body and in *the middle meatus, especially in the region of the hiatus* semilunaris While there may be some softening and degeneration of the middle turbinated bone, the bony structures of the ethmoid are not involved to an appreciable extent The condition may be accompanied by a purulent discharge from the surface of the polypi, but there is no suppuration from the ethmoidal cells

2 Deep seated hyperplastic ethmoiditis, non suppurative This condition involves the lateral mass of the ethmoid bone to a varying degree in extreme cases all of the ethmoidal cells being degenerated to the lamina papyracea of the orbit In operating on such ethmoid bones it is found that the entire middle turbinated body and the walls of the ethmoidal cells have become softened and partly absorbed by rarefying osteitis, so that the punch forceps penetrates with ease into the unresisting body of the ethmoid bone until its arrival on firm bone indicates the proper limit for the extirpation These are the cases in which the mere removal of polypi is useless and is promptly followed by a new crop, unless the diseased portion of the ethmoid bone furnishing it be cut out, if necessary, to the orbital wall

3 Deep seated suppurative ethmoiditis In this form numerous ethmoidal cells may be found filled with pus Otherwise, in my experience, the appearance is the same as in the non suppurative hyperplastic variety

I do not find that atrophy is a common accompaniment of ethmoidal suppuration On the contrary, I often find the hyperplastic type of the disease suppurative, as mentioned Atrophy of the ethmoid bone and its appendages does occur in the distinct affection called atrophic rhinitis, but atrophic rhinitis causes atrophy of the bony structures of the entire nasal interior as well and I have not found suppuration of the ethmoidal cells characteristic of atrophic rhinitis Ethmoiditis usually occurs in adults, while atrophic rhinitis is peculiar to adolescence, and is found especially in young girls I have found polypoid hyperplasia far more common in suppurative ethmoiditis than atrophy of the ethmoidal structures

Dr W L Ballenger, Chicago The point of the paper that impresses me is this The essayist divided ethmoiditis *into two types, the hyperplastic* and the suppurative Now then it seems to me he doesn't make it very clear why he so divides it As I understand hyperplastic rhinitis, or the polyp type of ethmoiditis, I should say it is due to an infection just as is the suppurative type, the active etiologic cause is infection Of course we have all degrees, from the very mild to the very severe infections, in one little or no purulent secretion, and in the other very pronounced secretion Now hyperplasia is surely due to a mild form of irritation or infection The suppurative type is due to a more virulent infection With a very mild infection the pathologic change is one of hyperplasia In the more active infection hyperplasia does not take place, but there is a sclerotic condition In the hyperplastic type we have a low grade of *inflammation*, and the tissue remains loose and is not compact, as in the more active type of inflammation In the lower grades, however, we may have and do have some purulent secretion, it may at times be purely mucus I have found that on first examination I may not find pus, but when I ask the patient if he has a yellow discharge from the nose it seems to me I have almost invariably found that he does, especially in the morning when he first gets up, so that I am rather of the opinion that even the hyperplastic type is attended by a mucopurulent secretion almost constantly, although it may not be observable in the nose on examination

Now both types of ethmoiditis are due to infection; in one instance a very low grade of inflammation and in the other *a more active type* With the lower grade we get hyperplasia and with the other we get a more active inflammation, with more secretion and with fibrous tissue formation.

Dr Ross Hall Skillern, Philadelphia: As to Dr. Ballenger's remarks, I might state that it was his skepticism that prompted me to present this paper I thought it might be a good thing to bring the slides out in this way for his inspection He seems to be at least half convinced, and I hope that time will further convince him

The latter part of the paper, which I did not have opportunity to read, answers Dr Casselberry's remarks in a brief way These pictures are not complete, as it requires a large number of fields to demonstrate thoroughly every condition The main purpose of the demonstration is to show that chronic hyperplastic ethmoiditis and chronic suppurative ethmoiditis are two separate and distinct pathologic processes.

Dr Ballenger asks *how the conclusion is reached* that these two conditions are primarily separate and distinct. He speaks about the infection caused by micro organisms; that I think is questionable. If one takes it that all diseased conditions are due to pathologic organisms he is right Recently I have had occasion to examine some of the so called bone cysts of the middle turbinate and found hyperplastic ethmoiditis just where the mucous membrane came in contact with the inspired air, the anterior *end* of the middle turbinate. *From* this fact it appears to me that this hyperplasia may be due to the irritation of the inspired air without regard to germs which *may* find lodgment on the mucous surface. The bacteriology of sinus disease is, I think, more or less obscure at the present time, *although* we have *had* numerous investigators, particularly *among* our German brethren. I have done *some* of this work in the past six months, and have in only one instance been able to obtain a pure culture of one particular organism; there were four or five different micro organisms, some pathologic and some the ordinary non-pathologic bacteria. I think the time will come when the so called non pus-producing organisms will be shown to be capable of causing inflammation. It seems to me it may be possible that the bacillus of influenza may produce the *inflammation* and then when it has disappeared other non-pathogenic organisms keep up the *suppuration*. *If* that theory can stand it will explain a great many things regarding suppurative ethmoiditis Taking *into* consideration the fact that there is only a difference in degree between polypoid swelling and polyp formation of the nasal mucous membrane, it is not strange that true polyp *formation* of the ethmoid may be observed without any empyema of the sinuses existing.

A Social Question.—Tuberculosis is no longer a medical problem; it is a great social question. Given public cooperation, in another generation it will pass away and be but a terrible memory—Martin Cooley, *Jour. Outdoor Life*, October.

TUBERCULOSIS OF THE ANKLE-JOINT AND TARSUS

JAMES WARREN SEVER, M.D.
Junior Assistant Surgeon, Children's Hospital
BOSTON

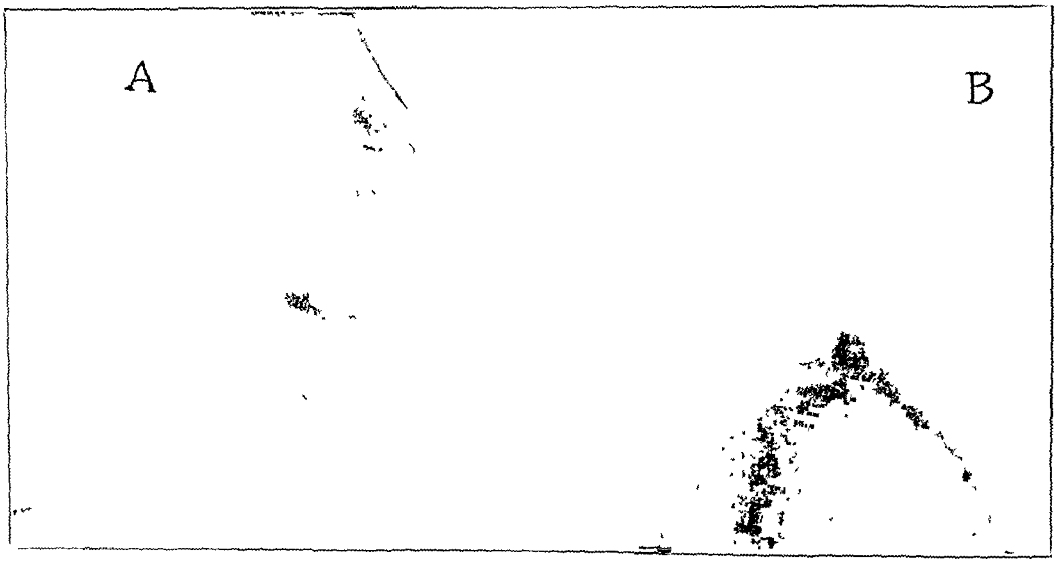

Fig 1—Ankle joint of A S, aged 1½ years. A lateral view of ankle, with destruction of upper portion of astragalus B antero posterior view of same foot The patient had an abscess opened in front of the external malleolus in November 1908. In May, 1910, there was slight bony thickening about the ankle, and considerable soft part thickening All motions were normal at the ankle joint. Patient toes in slightly; no valgus, no pain.

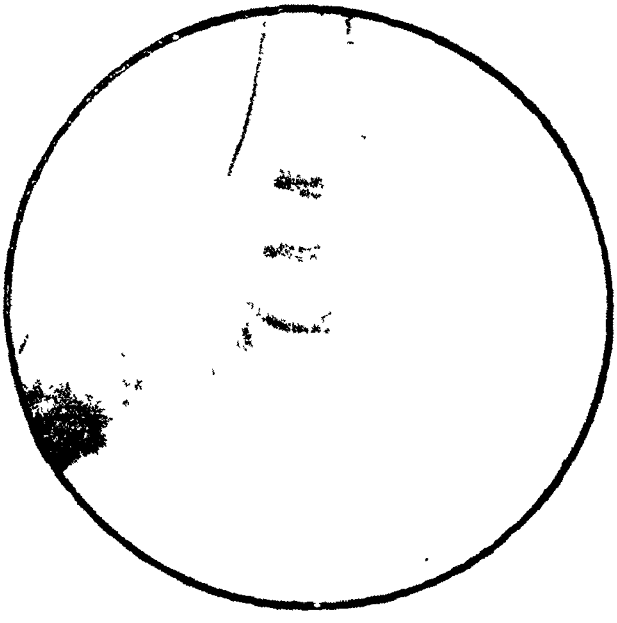

Fig 2—Ankle joint of W M, from x ray taken March, 1910 Tuberculous astragalus Excision of astragalus, March 31, 1908 Good motion at ankle Foot one inch shorter than right Slight pronation. No marked increase in lateral mobility

According to Thatcher in his "Modern Practice," published in 1826, "tuberculosis, scrofula, or 'the king's evil,'" is in its nature peculiarly inveterate, and is most generally handed down by parents to their offspring. Children possessing the most lively disposition and a maturity of understanding superior to others of their age, are those most liable to scrofula. It most commonly affects children of a lax habit, with smooth, fine skin, fair hair and rosy cheeks. It seldom makes its appearance before the second year of age, generally from the third to the seventh, and rarely makes its first attack after puberty."

In many ways this is to-day a correct picture of a case of bone or joint tuberculosis, varying somewhat, of course, in different cases.

Tuberculosis of the ankle-joint and the bones of the foot is much more frequent in children than in adults, and follows next in frequency tuberculous disease of the spine, hip or knee. Affecting bones and joints which have to bear weight, its treatment and course are necessarily much more difficult and protracted than in joints such as the elbow and shoulder. Also, owing to the superficial position of the bones of the foot, abscess formation is more noticeable and subsequent operation usually more often indicated.

Since 1868 there have been recorded at the Children's Hospital 213 cases of tuberculosis of the ankle-joint and bones of the foot. These cases have occurred in a clinic of 7,474 cases of bone and joint tuberculosis, showing a much larger proportion of cases than was shown in the occurrence of tuberculosis of the shoulder or elbow-joint. The cases of tuberculosis of the shoulder and elbow-joint have been reported by me in two recent papers.

Table 1 gives the data in regard to these cases, with the accompanying complications:

TABLE 1.—GENERAL STATISTICS OF 213 CASES OF ANKLE-JOINT TUBERCULOSIS

Total cases	213	Right ankle alone	108
Boys	122	Left ankle alone	90
Girls	91	Both ankles	15

Family history tuberculous	41
History of trauma	27
Average age at entrance	4.8 years

Average duration of disease at time of appearance at hospital, 9.3 months (197 cases).

Complications—

Ankle and hand (wrist and dactylitis)	15
Ankle and hip	6
Ankle and both knees	1
Ankle and knee	3
Ankle, knee and elbow	1
Ankle and elbow	1
Ankle and shoulder	1
Ankle and spine	9
Ankle and tuberculous peritonitis	1
Ankle with multiple tuberculosis with skin lesions and glands	11
	49

As will be seen, there were a few more boys affected than girls, probably owing to their greater exposure to trauma; a tuberculous family history was important; and about a fourth of the patients had other joints involved. Also it should be noted that a long time elapsed from the onset of the disease—that is, the time the parents first noticed that there was something wrong with the foot—until they brought the child to the hospital for treatment. This delay is often due to lack of responsibility on the part of the parents, and again to mistaken diagnosis on the part of the family physician, who believes the condition to be a chronic sprain or a rheumatic condition. It also points forcibly to the insidious and slow nature of the process. The average age in these cases, it will be noticed, was 4.8 years, as compared with the average age of patients with tuberculous shoulder of 4.7 years, and the average age of patients with tuberculous elbow of 5.3 years, which have been previously reported.

From a study of these cases in regard to their complications, and so far as I have been able to tell from their records, there has been about an equal frequency of the spread of the tuberculous infection from the ankle to the other joints and *vice versa.* The rapidity of the secondary involvement of the other joints has been increased following operation on the original focus, usually a curettage, while on the other hand, without operation, other joints have not become involved until several years have passed, in some instances extending up to five, six and ten years. Trauma to an apparently healthy joint in a child with a preexistent tuberculous joint often leads to the origin of a tuberculous focus in that joint. It would seem that unless an excision were done with as little mutilation as possible of the parts affected there was great danger of an extension of the tuberculous process to other joints, whereas with conservative treatment such extension is unlikely to occur, except after a long time, and especially in cases which present sinuses.

The onset is usually slow in these cases, and may follow an injury, such as a blow or a sprain. Any sprain which does not clear up promptly under the usual measures should make one most suspicious of some other process going on. Swelling follows about the part involved. If the disease is in the astragalus or the lower end of the tibia or fibula, there is swelling about the ankle-joint, often to such an extent that the outlines of the malleoli are obliterated. Where the tarsal or metatarsal bones are involved the swelling is more defined and localized over that area.

Limp and muscle spasm are noticeable, especially in disease of the ankle-joint. Motion is limited, especially in plantar and dorsal flexion. Where the tarsal bones are involved there is usually very little spasm, and the joint motions are practically normal, unless the process is most extensive. There is, of course, the subsequent atrophy of the leg from disuse.

The swelling is usually not a fluctuating one, but is doughy and gelatinous in feeling.

The most frequent location of the disease is in the astragalus, followed in order of occurrence by the os calcis and lower end of the tibia, lower end of the fibula, scaphoid, cuboid and first metatarsal. These joints are working centers of weight-bearing, and subject to constant friction, strain, over-use and general wear and tear, and joints which transmit weight to the ground are usually more subject to strain, injury and disease than others.

The location of the disease in the different bones is shown by Table 2.

TABLE 2.—LOCATION OF DISEASE (BY OPERATION OR X-RAY)

Astragalus	74
Os calcis	45
Scaphoid	14
Cuboid	14
Tibia (lower end)	42
Fibula (lower end)	19
Internal cuneiform	6
Middle cuneiform	6
External cuneiform	5
First metatarsal	12
Second metatarsal	5
Third metatarsal	4
Fourth metatarsal	2
Fifth metatarsal	4
	252
Occurring in more than 1 bone	40

When the astragalus is involved it is usually its upper surface, which leads to involvement of the whole joint, including the lower ends of the tibia and fibula. Areas in the os calcis are more usually localized, do not involve the joint, and are as a rule not as serious an affection, unless the disease is virulent and attacks other bones.

prompted me to present this paper. I thought it might be a good thing to bring the slides out in this way for his inspection. He seems to be at least half convinced, and I hope that time will further convince him.

The latter part of the paper, which I did not have opportunity to read, answers Dr. Casselberry's remarks in a brief way. These pictures are not complete, as it requires a large number of fields to demonstrate thoroughly every condition. The main purpose of the demonstration is to show that chronic hyperplastic ethmoiditis and chronic suppurative ethmoiditis are two separate and distinct pathologic processes.

Dr. Ballenger asks how the conclusion is reached that these two conditions are primarily separate and distinct. He speaks about the infection caused by micro-organisms; that I think is questionable. If one takes it that all diseased conditions are due to pathologic organisms he is right. Recently I have had occasion to examine some of the so-called bone-cysts of the middle turbinate and found hyperplastic ethmoiditis just where the mucous membrane came in contact with the inspired air, the anterior end of the middle turbinate. From this fact it appears to me that this hyperplasia may be due to the irritation of the inspired air without regard to germs which may find lodgment on the mucous surface. The bacteriology of sinus disease is, I think, more or less obscure at the present time, although we have had numerous investigators, particularly among our German brethren. I have done some of this work in the past six months, and have in only one instance been able to obtain a pure culture of one particular organism; there were four or five different micro-organisms, some pathologic and some the ordinary non-pathologic bacteria. I think the time will come when the so-called non-pus-producing organisms will be shown to be capable of causing inflammation. It seems to me it may be possible that the bacillus of influenza may produce the inflammation and then when it has disappeared other non-pathogenic organisms keep up the suppuration. If that theory can stand it will explain a great many things regarding suppurative ethmoiditis. Taking into consideration the fact that there is only a difference in degree between polypoid swelling and polyp formation of the nasal mucous membrane, it is not strange that true polyp formation of the ethmoid may be observed without any empyema of the sinuses existing.

A Social Question.—Tuberculosis is no longer a medical problem; it is a great social question. Given public cooperation, in another generation it will pass away and be but a terrible memory—Martin Cooley, *Jour. Outdoor Life*, October.

TUBERCULOSIS OF THE ANKLE-JOINT AND TARSUS

JAMES WARREN SEVER, M.D.
Junior Assistant Surgeon, Children's Hospital
BOSTON

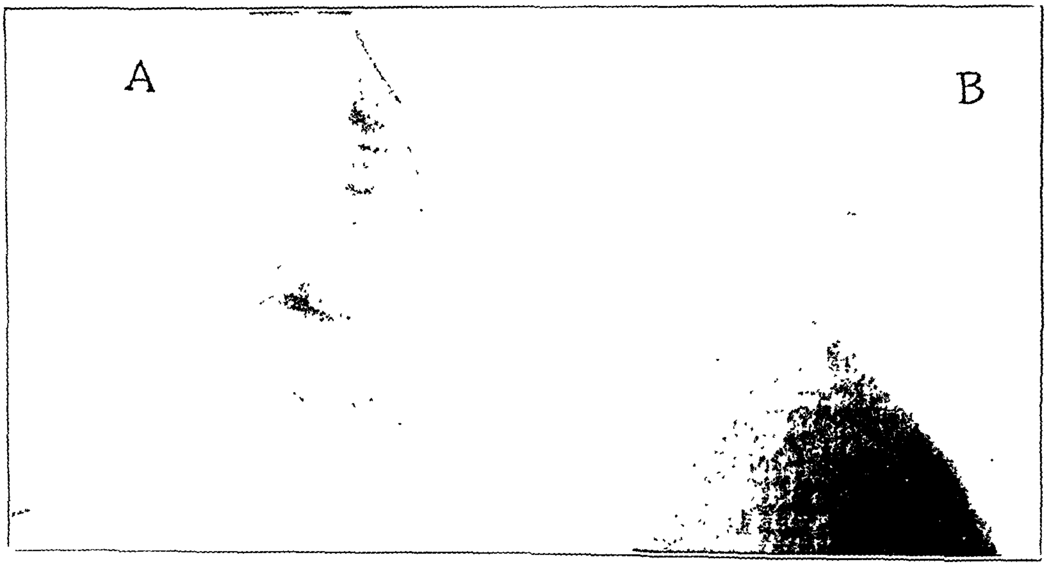

Fig 1.—Ankle-joint of A. S., aged 1½ years. A, lateral view of ankle, with destruction of upper portion of astragalus. B, anterio-posterior view of same foot The patient had an abscess opened in front of the external malleolus in November, 1908. In May, 1910, there was slight bony thickening about the ankle, and considerable soft part thickening All motions were normal at the ankle-joint. Patient toes in slightly; no valgus, no pain.

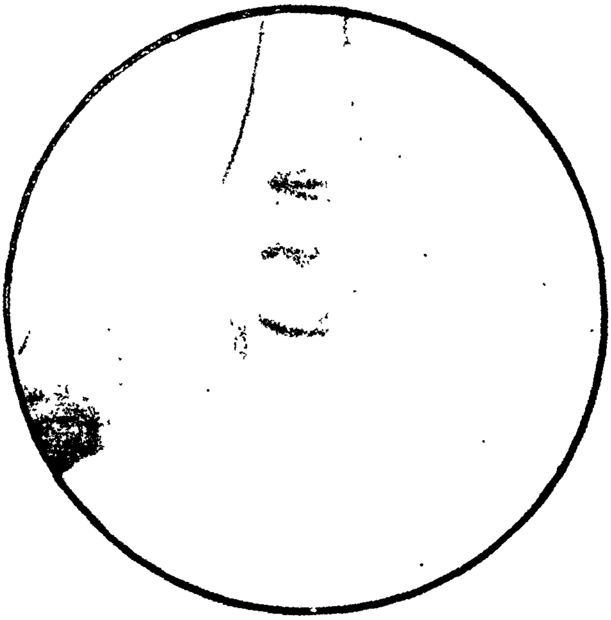

Fig. 2.—Ankle-joint of W. M., from *x*-ray taken March, 1910. Tuberculous astragalus. Excision of astragalus, March 31, 1908. Good motion at ankle. Foot one inch shorter than right. Slight pronation. *No* marked increase in lateral mobility.

According to Thatcher in his "Modern Practice," published in 1826, "tuberculosis, scrofula, or 'the king's evil,'" is in its nature peculiarly inveterate, and is most generally handed down by parents to their offspring. Children possessing the most lively disposition and a maturity of *understanding* superior to others of their age, are those most liable to scrofula. It most commonly affects children of a lax habit, with smooth, fine skin, fair hair and rosy cheeks. It seldom makes its appearance before the second year of age, generally from the third to the seventh, and rarely makes its first attack after puberty."

In many ways this is to-day a correct picture of a case of bone or joint tuberculosis, varying somewhat, of course, in different cases.

Tuberculosis of the ankle-joint and the bones of the foot is much more frequent in children than in adults, and follows next in frequency tuberculous disease of the spine, hip or knee. Affecting bones and joints which have to bear weight, its treatment and course are necessarily much more difficult and protracted than in joints such as the elbow and shoulder. Also, owing to the superficial position of the bones of the foot, abscess formation is more noticeable and subsequent operation usually more often indicated.

Since 1868 there have been recorded at the Children's Hospital 213 cases of tuberculosis of the ankle-joint and bones of the foot. These cases have occurred in a clinic of 7,474 cases of bone and joint tuberculosis, showing a much larger proportion of cases than was shown in the occurrence of tuberculosis of the shoulder or elbow-joint. The cases of tuberculosis of the shoulder and elbow-joint have been reported by me in two recent papers.

Table 1 gives the data in regard to these cases, with the accompanying complications:

TABLE 1.—GENERAL STATISTICS OF 213 CASES OF ANKLE-JOINT TUBERCULOSIS

Total cases	213	Right ankle alone	108
Boys	122	Left ankle alone	90
Girls	91	Both ankles	15

Family history tuberculous	41
History of trauma	27
Average age at entrance	4.8 years

Average duration of disease at time of appearance at Hospital, 9.3 months (197 cases).

Complications—

Ankle and hand (wrist and dactylitis)	15
Ankle and hip	6
Ankle and both knees	1
Ankle and knee	3
Ankle, knee and elbow	1
Ankle and elbow	1
Ankle and shoulder	1
Ankle and spine	9
Ankle and tuberculous peritonitis	1
Ankle with multiple tuberculosis with skin lesions and glands	11
	49

As will be seen, there were a few more boys affected than girls, probably owing to their greater exposure to trauma; a tuberculous family history was important; and about a fourth of the patients had other joints involved. Also it should be noted that a long time elapsed from the onset of the disease—that is, the time the parents first noticed that there was something wrong with the foot—until they brought the child to the hospital for treatment. This delay is often due to lack of responsibility on the part of the parents, and again to mistaken diagnosis on the part of the family physician, who believes the condition to be a chronic sprain or a rheumatic condition. It also points forcibly to the insidious and slow nature of the process. The average age in these cases, it will be noticed, was 4.8 years, as compared with the average age of patients with tuberculous shoulder of 4.7 years, and the average age of patients with tuberculous elbow of 5.3 years, which have been previously reported.

From a study of these cases in regard to their complications, and so far as I have been able to tell from their records, there has been about an equal frequency of the spread of the tuberculous infection from the ankle to the other joints and *vice versa.* The rapidity of the secondary involvement of the other joints has been increased following operation on the original focus, usually a curettage, while on the other hand, without operation, other joints have not become involved until several years have passed, in some instances extending up to five, six and ten years. Trauma to an apparently healthy joint in a child with a preexistent tuberculous joint often leads to the origin of a tuberculous focus in that joint. It would seem that unless an excision were done with as little mutilation as possible of the parts affected there was great danger of an extension of the tuberculous process to other joints, whereas with conservative treatment such extension is unlikely to occur, except after a long time, and especially in cases which present sinuses.

The onset is usually slow in these cases, and may follow an injury, such as a blow or a sprain. Any sprain which does not clear up promptly under the usual measures should make one most suspicious of some other process going on. Swelling follows about the part involved. If the disease is in the astragalus or the lower end of the tibia or fibula, there is swelling about the ankle-joint, often to such an extent that the outlines of the malleoli are obliterated. Where the tarsal or metatarsal bones are involved the swelling is more defined and localized over that area.

Limp and muscle spasm are noticeable, especially in disease of the ankle-joint. Motion is limited, especially in plantar and dorsal flexion. Where the tarsal bones are involved there is usually very little spasm, and the joint motions are practically normal, unless the process is most extensive. There is, of course, the subsequent atrophy of the leg from disuse.

The swelling is usually not a fluctuating one, but is doughy and gelatinous in feeling.

The most frequent location of the disease is in the astragalus, followed in order of occurrence by the os calcis and lower end of the tibia, lower end of the fibula, scaphoid, cuboid and first metatarsal. These joints are working centers of weight-bearing, and subject to constant friction, strain, over-use and general wear and tear, and joints which transmit weight to the ground are usually more subject to strain, injury and disease than others.

The location of the disease in the different bones is shown by Table 2.

TABLE 2.—LOCATION OF DISEASE (BY OPERATION OR X-RAY)

Astragalus	74
Os calcis	45
Scaphoid	14
Cuboid	14
Tibia (lower end)	42
Fibula (lower end)	19
Internal cuneiform	6
Middle cuneiform	6
External cuneiform	5
First metatarsal	12
Second metatarsal	5
Third metatarsal	4
Fourth metatarsal	2
Fifth metatarsal	4
	252
Occurring in more than 1 bone	40

When the astragalus is involved it is usually its upper surface, which leads to involvement of the whole joint, including the lower ends of the tibia and fibula. Areas in the os calcis are more usually localized, do not involve the joint, and are as a rule not as serious an affection, unless the disease is virulent and attacks other bones.

Either the lower end of the tibia or fibula, near or at the epiphyseal line, may be the starting point of the disease, which then usually spreads to the whole ankle-joint. Swelling localized about the internal malleolus usually points to a focus in the tibia, and swelling about the external malleolus to a focus in the epiphysis of the lower end of the fibula. Swelling which obliterates both malleoli usually means that the astragalus is involved, or at least the synovia covering it, as well as the lower ends of the tibia and fibula.

Marked swelling over the neck of the astragalus, and most prominent on the dorsum of the foot, usually points to an active process in that region, which later will probably extend and involve the ankle-joint. (See Fig. 1.)

Foci of disease originating in the other tarsal and metatarsal bones of the foot are not frequent, and may often be limited to the bone in which they originate, or, if the virulence of the infection is great, may rapidly spread to the other bones and so involve the whole foot. In children the tarsal and metatarsal bones are largely cartilaginous, and so have slight resisting power and disintegrate rapidly, especially provided no treatment is undertaken from the start.

Abscesses occur frequently, and this is probably explained by the superficial position and small size of the bones involved, which conditions cause an abscess to form and break before the healing process of reabsorption has a chance to take place, as would happen in bones and joints of larger size in which the focus of disease is more deeply situated.

Following the opening of an abscess, a sinus usually persists. Spontaneous rupture of an abscess is not rare, and many cases of this series presented themselves at the hospital following such a rupture, and with a discharging sinus. In these cases a mixed infection is the usual condition to be combated, and adds to the risk of any curetting operation.

Sinuses persisting after operation are not rare, but their presence depends a good deal on the extent of the operative proceedings and the number and area of bones involved. A clean excision of a single bone with a single sinus, even if long-existent, which removes practically all the disease, should lead one to expect a first-intention wound, without subsequent breaking down, provided the after-treatment is carefully and properly carried out. In this series of cases there were forty patients in whom the disease had attacked more than one bone of the foot.

DIAGNOSIS

The diagnosis of tuberculous disease of the ankle-joint or tarsus is usually easily made. The cardinal symptoms are pain, soreness, limp, swelling, muscle spasm. When the ankle-joint is involved, and when the disease has existed for any length of time, the foot is usually held in slight plantar flexion, with obliteration of the outlines of the malleoli, and occasional inversion of the foot. Increased surface temperature is practically always present and redness when the disease is in one of the smaller superficial bones, or when an abscess has formed.

Chronic sprain, irritable flat-foot, syphilis and infectious arthritis are to be ruled out by the history, x-rays and results of treatment. It is usually not difficult for one familiar with these conditions to make a correct diagnosis. Osteomyelitis may be confused with an active tuberculous process, but presents the picture of a much more rapid and virulent infection, which requires immediate operative interference. Disease in the tarsal bones may be localized to one bone, and may be evident on inspection. Also it may have spread and involved the whole tarsus so that the whole dorsum of the foot is swollen, boggy and hot.

Disease of the lower end of the tibia, fibula or astragalus quickly involves the ankle-joint and causes the characteristic swelling about the malleoli, the outlines of which are obliterated.

PATHOLOGY

The pathology of tuberculosis of the bones of the foot is like that of all other bone tuberculosis. Ely states, in defining tuberculosis of the joints, that it is a reaction of the tissues in and about a joint to the presence of the tubercle bacillus or its toxins. He believes strongly in primary infection of the synovia, followed by extension from the synovia to the cartilage and bone. Nichols, on the other hand, believes that all joint tuberculosis is of primary bony origin, starting at the epiphyseal lines in the bone marrow and invading the joint secondarily.

The bacillus usually enters the respiratory tract, or may be in the intestinal tract, when it is usually derived from infected milk. The tonsils are also to be considered as channels of infection. At autopsy the foci are usually found in the lungs, intestines, bronchial and mesenteric lymph-nodes. General tuberculosis may result from a local bone infection, provided the process is active and virulent and the patient's resistance is below par. It may also follow after a curetting operation on the focus, or in a case which has had multiple sinus of long standing.

Following a mild injury there is an inflammatory exudate which offers the tubercle bacilli a favorable field for growth if it is already present in the body; while if the injury is severe the reparative processes are so active that the bacillus is destroyed even if it does obtain access to the injured part.

When the bones of the foot are affected there is the usual formation of the tubercle, which breaks down and becomes caseous, owing probably to the lack of blood-vessels in the destructive process, and also to the action of the soluble toxins produced by the tubercle bacillus.

As I have noted before, these caseous masses, being in bones which are small and superficial, readily appear under the skin, as abscesses. They may remain single or spread and coalesce, and cause extensive destruction of various adjacent bones of the foot.

Repair is brought about by formation of fibrous tissue which replaces or partly encapsulates the tuberculous tissue. This may become ossified, and so may result in bony anchylosis of the part involved.

In detail the histogenesis of the tuberculous process is as follows, as shown by Kertesz through experiments on rabbits:

> Tubercle bacilli introduced into the bone-marrow of rabbits are quickly surrounded by polymorphous leukocytes, and they, as well as a portion of the fixed connective tissue cells situated in the district invaded, are destroyed within two or three days. Another portion of the fixed connective tissue cells, as well as the desquamated endothelial cells of the capillaries, increase amitotically. These cells, as well as the young proliferated elements, group themselves about the tubercle bacilli and form the epithelioidal tubercle, which is completely formed as early as the fourth day. The first tuberculous giant cells appear on the fifth day, originating at this stage through a confluence of the augmented endothelium of the capillaries.
>
> On the seventh day lymphocytes group themselves about the tubercle, which latter at this time already shows signs of caseation in its center. On the eighth day the lymphocytes

penetrate the tubercle. The leukocytes do not reach the neighborhood of the bacilli in their initial accumulation from the blood-vessels, but rather from the septa of the neighboring bone marrow. The lumina of the capillaries in the neighborhood of the tuberculous tissue are obliterated either through pressure, or they disappear through the desquamation of the endothelium, which then begins to proliferate. The accumulation about, and the migration into the tubercle on the seventh or eighth day, takes place also from the neighboring bone marrow. The connective tissue elements of this tissue proliferate. It is probable that this increase in connective tissue produces the obliteration in the blood spaces. Redestruction of the tubercle, its coagulation necrosis, is caused therefore, not considering the toxins of the bacilli, by the obliteration of the capillaries and the blood-spaces in its neighborhood.

TREATMENT

The treatment in this series of cases has been operative and non-operative.

Before taking up the results in these two classes of *cases I wish to give the outlines of the routine treat*ment. Given a case of tuberculosis of the ankle or tarsus, the two most essential things to do are to prevent weight-bearing and to enforce absolute rest. These two conditions are the *sine qua non* in the treatment of any tuberculous joint condition, and without them very little is to be expected either for a cure or for a good satisfactory result.

The general condition is most important also, and a healthy, restful, outdoor life, with plenty of nourishing food, is essential.

With disease in the bones and joints considerable variation occurs in the virulence of the infection and the resistance of the individual, and where in one case acute and destructive disease exists, causing great impairment of function, in another the disease may run a very mild course and leave the patient with nearly a normal joint. There is no way of telling at first, however, which type exists, and so the routine is to be carried out in each case. The use of tuberculin in this series of cases of surgical tuberculosis has not been tried. In view of the experience of others, however, it would seem that it is of use in certain cases, and certainly shortens the convalescent period.

Bier's passive congestion method has also proved to be of use, in the hands of others, who state that the course of the disease is shortened, and that a better functional result is obtained.

In order to get relief from weight-bearing and to insure rest of the part, a plaster cast is applied, with the foot at a right angle to the leg, from the toes to the knee. The child is then fitted to a Thomas knee splint, on which he may walk. He is also provided with a high sole and crutches. This is the routine outfit, and is all that has been used in this series of cases, for protection and fixation of the joint.

As in all tuberculous bone disease in children, the great question arises: Is conservative treatment—that is, absolute rest and fixation—better than operative interference—that is, curettage of the focus, or excision of the whole affected bone or bones?

The only way that this question can be answered is by a study of a large number of cases and statistics, with final results. By presenting figures which cover these points I shall endeavor to show that there is a distinct advantage in children, at least, by pursuing a conservative plan, both as to the result as far as function is concerned, and also in time saved.

Table 3 shows the list of operations performed in this series of cases.

TABLE 3.—LIST OF OPERATIONS FOR TUBERCULOUS ANKLE-JOINT

Incision and curettage	46
Astragalectomy	45
Removal of scaphoid	5
Removal of os calcis	15
Removal of cuboid	6
Removal of lower end of fibula	14
Removal of lower end of tibia	11
Internal cuneiform excised	2
Middle cuneiform excised	2
External cuneiform excised	2
First metatarsal excised	2
Second metatarsal excised	0
Third metatarsal excised	1
	156

Taking the ankle-joint first, the records show that it was involved by operation seventy times, including the astragalus and lower ends of the tibia and fibula. This total covers operations for purposes of bone excision, of one or more bones, or parts of bones. This leaves a total of only forty for the other cases of bone excisions, not involving the ankle-joint. The opening and curetting *of abscesses in this series amounted to a total of forty-*six cases. These operations on abscesses were not done until absolutely necessary, and were done simply for drainage purposes. I have not attempted to classify them, as the resultant data would be of no great significance.

In the operative cases, where nearly twice as many operations were done which involved the ankle-joint, the known results are as follows:

TABLE 4.—RESULTS OF OPERATION

Motion—	
Good	29
Slight	22
None	47
	98
Deformity—	
None	7
Thickening about malleoli	65
Inversion of foot	2
Equinovalgus	10
Shortening of foot	17
Equinovarus	5
Calcaneus	2
	101

These results include forty-five excisions of the astragalus, fourteen operations for the removal of the lower end of the fibula and eleven operations for the removal of the lower end of the tibia.

In the operative cases the average duration of the disease from its onset until treatment was discontinued was 19.8 months (in 114 cases). The average duration of the treatment was 10.1 months. Of the operative cases there were 72 in which there was 1 operation; 17 in which there were 2 operations; 16 in which there were 16 operations; 8 in which there were 4 operations; 1 in which there were 5 operations.

The necessity of operating on a patient more than once depends wholly on the virulence of the disease, the rapidity of its extension, and the extent of the operation done. A number of cases which have only an abscess opened at one time may need later operations for other abscesses, enlarging a sinus, or the later removal of a sequestrum or an entire bone.

In this operative list is also included the few operations which were done on the bones of the foot which did not involve the ankle-joint.

The non-operative results appear in Table 5.

These are the results in those cases which were treated by fixation, rest and protection only until the process had healed. The average duration of the disease in these cases from onset until cessation of the treatment was 16.1 months in 99 cases. The *average duration of* the treatment was 6.8 months, giving an average in favor of the non-operative series of 3.3 months from the beginning of the treatment until it was no longer necessary.

TABLE 5.—RESULTS IN NON-OPERATIVE CASES

Motion—	
Good	32
Slight	23
None	33
	88
Deformity—	
None	4
Plantar flexion	1
Thickening	63
Equinovalgus	11
Calcaneovarus	2
Calcaneovalgus	1
Equinovarus	6
	88

From a study of these figures it will be noted that there was a distinct gain in time and also in the function and lack of deformity of the foot in the cases of the non-operative series. It is only natural to expect less deformity in a child's foot in which conservative measures have been followed than after the mutilation of an excision more or less extensive. The time saved is also of importance.

Scudder's conclusions in the series of eighteen cases reported in 1889, which are included in this report, cannot be admitted in view of these later figures. Radical operations on joints and bones in children are not the best methods of treatment, and conservative measures are to be carried out until radical operation is indicated, when all else has failed to stop the progress of the disease.

TABLE 6.—DEATHS IN CASES OF ANKLE-JOINT TUBERCULOSIS

Years of Age.	Time of Death from First Appearance of Disease.	No. of Operations.	Last Operation Before Death.	Condition of Ankle at Death.	Cause of Death.
3	1 year	2	Few months	Not healed	T. B. meningitis.
4	5 months	2	2 days	Not healed	Shock.[1]
2¼	1 year	2	10 days	Not healed	T. B. meningitis.[2]
3	1½ to 2 years.	1	1 year	Healed	T. B. meningitis.
12	2½ years	1	2 years	Healed	T. B. meningitis.
1½	Few months	1	Few months.	Not healed	T. B. meningitis.
4	11 months	0	No operation	Healed, swollen	T. B. meningitis.
2	16 months	0	No operation	Not healed	T. B. meningitis.[3]
3	20 months	1	4 months	Not healed	Gen. T. B.[4]
1	4 years	2	4 years	Healed	Gen. T. B.[5]
9	2 years	3	6 weeks	Not healed	Gen. T. B.[6]

1. First operation astragalus. Part of os calcis, scaphoid and head of ulnar removed. Second operation os calcis curetted.
2. Astragalus and cuboid removed.
3. Eight to ten sinuses about ankle. No operation. Both ankles.
4. Astragalus and scaphoid curetted. Amyloid.
5 Developed lumbar tuberculosis three years later with abscesses, which were opened one and two years before death. Amyloid.
6. T. B. lungs, liver, appendix, mesenteric glands.

Operations, then, should be clean. No curetting should be allowed, and any bone or bones involved should be removed *in toto,* with as little mutilation as possible. The increased risk of deformity after an excising operation is, of course, obvious, whereas the non-operative cases which go on to a cure are much less apt to result in deformity, and then not of so serious a nature.

When small foci exist in bones such as the os calcis, the cuboid, the scaphoid and the cuneiform, which are not very active, a conservative course is to be followed. If the process is active and acute, often an incision to establish drainage will prevent extensions, and give the part an opportunity to heal, but removal of the whole bone is not to be practiced unless the destruction is great, the process spreading, or of long duration with a persistent sinus, for the subsequent deformity is of course greater. In some instances subperiosteal excision may be done, which allows the cavity to become filled with new bone in a shorter time than it would otherwise. In other cases the sinus may be probed out, the sequestrum removed, and the bone cavity carefully wiped out with phenol, followed by alcohol, or tincture of iodin may be used. Occasionally a first-intention wound is obtained after this procedure.

DEFORMITIES

Following a cure in either an operative or non-operative case there may be deformity which needs correction. This is to be done by appropriate tenotomies or osteotomies, a sufficiently long time having elapsed to avoid any further lighting up of the original disease. The foot is then to be held in the correct weight bearing position. In looking at Tables 4 and 5 one may see the deformities following the two classes of operative and non-operative cases as far as I have been able to collect reports of them. It is to be noted that the most common result was thickening about the malleoli. This thickening is practically always bony in character, and is due to the deposit of new bone laid down in the healing process.

There is usually also some shortening of the foot from atrophy of disuse, which is generally slight, and also from removal of bone. The shortening is usually most marked when the astragalus has been removed. The other deformities noted are due in part to excisions of various bones and contractions of the soft parts, and rarely follow any rule.

The motion noted is to be interpreted as follows: "Good" means normal to one-half normal; "slight" means 10 degrees to 20 degrees normal. In cases in which certain joints are ankylosed, neighboring joints take up their work and increase their range of motion, so that there is always a certain amount of compensation. For instance, if the ankle-joint is ankylosed, the tarsometatarsal joints will increase their range of motion to such an extent that there is considerable freedom in that joint, which condition of course makes for more ease and freedom in walking and a more flexible foot.

CAUSES OF DEATH

Including Dr. Scudder's six cases reported in 1889, in this series I have been able to find but a total of eleven deaths. Nine of this series were operative cases, the deaths occurring from either tuberculous meningitis, shock or a generalized tuberculosis, at varying intervals after the operation. Some could be attributed directly to the operation as a cause, but others were too remote to lead one to suspect that operation was a factor. These cases are shown in detail in Table 6.

CONCLUSIONS

Tuberculosis of the ankle-joint and bones of the foot in children is insidious in its onset, chronic in its course, and attacks usually young children.

The expectant or conservative method of treatment is preferable to the operative one.

Time is saved and deformity less under the conservative plan than by the operative method.

There is also less danger of secondary joint involvement and general tuberculosis by pursuing the nonoperative plan.

The disease may be associated with bone and joint tuberculosis in other parts of the body.

The prognosis is fairly good for life, but poor for a good ankle-joint in which there is no disability.

A certain number get a good functional ankle, with but slight deformity.

In regard to the smaller metatarsal bones the results are good for joint motion.

VARIOUS FORMS OF EXPERIMENTAL DIABETES AND THEIR SIGNIFICANCE FOR DIABETES MELLITUS*

J. J. R. MACLEOD, M.B., Ch.B., D.P.H.
CLEVELAND

In the short time allotted in this symposium to the study of experimental diabetes or glycosuria, I shall not of course attempt to give any general review of all the experimental conditions which may cause reducing substances to appear in the urine. It will be more profitable to devote the greater part of my time to a study of the simplest and best-known form of experimental glycosuria, namely, to that which results from stimulation of certain portions of the nervous system.

I shall, then, briefly consider the relationship to this comparatively simple form of glycosuria of some of the other experimental forms, such as those produced by asphyxia and by the influence of certain ductless glands. Its relationship to clinical diabetes I shall, however, omit, for the reason that there is very little definite information on which to base conclusions.

Before going farther, it may be well to call attention to the distinction that must be drawn between the terms "glycosuria" and "diabetes." The former denotes the presence of glucose or dextrose in the urine and is merely a symptom. The latter is the name applied to a group of symptoms of which glycosuria is one; it is the name of a disease. It is with the chemical pathology of the symptom, glycosuria, that we are to occupy our time.

So far as is known at present, there seem to be three distinctly different mechanisms by which dextrose may appear in the urine. In two of these the appearance of dextrose in the urine, the glycosuria, that is to say, is dependent on an increased percentage of dextrose in the blood. This hyperglycemia, as it is called, may be due either to increased production of dextrose by the liver or to diminished utilization of dextrose in the tissues. In the remaining form of experimental diabetes there is no hyperglycemia, the glycosuria being primarily due to a derangement of the renal function of such a nature as to cause the sugar normally present in the blood to be excreted into the urine.

It is, then, to the first of these three forms of experimental glycosuria that I shall devote most of my attention.

When we sift it down to its essentials we see that a study of this form of experimental diabetes means really a study of those conditions which so disturb the glycogenic function of the liver as to bring about an excessive conversion of its glycogen into dextrose. It may well be asked here of what value to the general question of diabetes such investigations can be. The great attention which has recently been given to the study of such forms of experimental diabetes as that which follows pancreatectomy, parathyroidectomy, epinephrin injection, phloridzin poisoning, etc., has drawn attention away from this simpler type defined above, and this, notwithstanding the well-known fact that at the outset of every form of diabetes there exists an excessive hepatic glycogenolysis. It is not far from the truth to state that in every variety of experimental diabetes there is an excessive production of sugar due to hepatic glycogenolysis; in some of them the glycosuria ceases when all the glycogen has disappeared; in others it persists, the dextrose being now derived from other sources than glycogen and being usually accompanied by a depressed glycolysis. Besides glycosuria other symptoms of diabetes make their appearance. In this latter group of cases the independence of the source of the sugar from the glycogenic function of the liver in the later stages has diverted attention from this function with the result that in seeking for the exact cause of the persistent production of dextrose by the organism, it is often lost sight of that the glycogenic function of the liver has been almost, if not entirely, thrown out of commission, as evidenced by the great poverty of glycogen, even after feeding with excess of dextrose-yielding food.[1] Loss of the power on the part of the tissue to destroy dextrose is usually given as the cause of the hyperglycemia, but the possibility that this is associated with a derangement of hepatic function is commonly overlooked. Hyperglycogenolysis is the first outcome of this derangement; may it not be that the subsequent inability to destroy dextrose in the organism, as well as the production of dextrose from protein, is also dependent on deranged hepatic function?

These preliminary remarks indicate the importance of a more thorough knowledge of the glycogenic function of the liver, and it is to what is already known of this and of the conditions which (apart from lesions elsewhere in the organism) may throw it out of gear that we shall now confine our attention.

SOURCE OF GLYCOGEN

In the short space of time at my disposal, there are of course several aspects of this glycogenic function which must be very cursorily considered and one of these is *the source of the glycogen*. There is now no doubt that besides the carbohydrates themselves, proteins may lead to glycogen deposition. The most satisfactory evidence on which this conclusion is based has been derived from metabolism studies in diabetic animals, it having been found in these that when proteins or certain of the degradation products of protein are ingested, an increase in the dextrose excretion occurs. The proteins are thus shown to be convertible in the organism into dextrose which, of course, means that, were the glycogenic function of the liver not deranged, they would have been converted into glycogen.[2, 3, 4]

What more particularly concerns us in the present connection is the fate of this glycogen. Following Bernard's teaching,[5] most authorities believe that glycogen is reconverted into dextrose, and delivered as such into the blood whenever that which is already present therein tends to fall below its normal percentage. When the tissues require more carbohydrate in the performance of their metabolic functions, they derive it from the blood which again replenishes its store from the glycogen of the liver; or, if this be all used up, from that also present in the muscles.

No one denies that before being utilized, the glycogen is reconverted into dextrose, but the English physician Pavy[6] has advanced the hypothesis that whenever the glycogen molecule becomes broken down into molecules of glucose, the latter, instead of becoming dissolved in the blood plasma, becomes instantly taken on as a "side-chain by a protein constituent of the blood." He was one of the first to demonstrate the existence of carbohydrate molecules among the degradation products of protein, and, disregarding the fact that it is mainly as glycosamin that these are present,[7] he concludes that they must represent the glucose, which in this form is being transported to the tissues to be utilized as fuel.

Pavy's chief argument against the reconversion of hepatic glycogen into free dextrose seems to be that dextrose could not exist in a free state in the blood on account of its being immediately excreted in the urine. "When circulating through the kidney," so he writes, "it [dextrose] cannot be prevented from escaping like other small molecular bodies and making its appearance in the urine." I have no time at my disposal to discuss this question at any length, and, indeed, it requires little discussion, for it has been unequivocally demonstrated by the recent work of Rona and Michaelis[8] that all the sugar in the blood exists therein in simple solution, some of it in the corpuscular contents, the remainder in the plasma. These workers have shown that when diluted blood is shaken with certain colloids, such as ferric hydroxid or kaolin, the proteins are all adsorbed (*i. e.*, form a colloidal combination) and can be quantitatively precipitated by the subsequent addition of a trace of electrolyte, but that not a trace of sugar is removed from solution by this treatment. Were the dextrose in any way united with the proteins, it would certainly be carried down along with them. Nor is it possible that there can be a disruption of any such compound by the above treatment, for the reagent employed cannot be imagined to have any disruptive action. Another piece of evidence in support of the free state of dextrose in blood is furnished by the observation that, whereas charcoal adsorbs both sugar and protein from a solution containing these two substances alone (*i. e.*, when it is shaken with a solution of protein and sugar), yet it adsorbs the protein but not the dextrose when acetone is present in the solution. The acetone being more adsorbable than the dextrose prevents the latter being taken up by the charcoal.[9] Further evidence of the free state of dextrose in the blood was furnished by dialysis experiments to discuss which, however, would occupy too much of our time.[10]

Under normal conditions this production of dextrose by the liver is finely adjusted so that the percentage in the blood is kept about the normal level, which is variously given as from 0.1 to 0.15 per cent. What is it, then, that regulates this amount? It cannot be because of a direct influence on the liver cell of the amount of dextrose in the blood, for, with the exception of that circulating in the hepatic artery, this passes to the liver through the portal system, in which it has added to it the dextrose absorbed by the intestine. Only two other possibilities remain open: direct action on the liver cells of some chemical constituents of the blood other than dextrose, or a nervous reflex.

Experimental evidence at present stands in favor of the latter view. The conversion of glycogen into dextrose or glycogenolysis, as we may call it, which is thus held in control during life, becomes very much exaggerated after death. In a few moments after the circulation of blood through the liver has ceased this glycogenolysis sets in and becomes more and more marked until, after about thirty-five to forty-five minutes, in the case of most livers, it has assumed enormous proportions, after which it gradually declines to disappear almost entirely some considerable time before all of the glycogen has been thus transformed.[11]

During life, an equally active glycogenolysis may be brought about by a variety of causes, but more especially by stimulation of certain portions of the nervous system. This causes an excess of dextrose to accumulate in the blood, hyperglycemia becomes established and as a consequence glycosuria. This is experimental glycosuria or diabetes.

There is nothing to indicate that any essential difference exists between ante-mortem and post-mortem glycogenolysis; in other words, there is a constant tendency for the liver to produce sugar from glycogen. During life this tendency is held in check by some inhibitory mechanism, the break-down or the removal of which is therefore the immediate cause of experimental diabetes. In the further development of the subject, it is from this view-point that I shall proceed, and the first question naturally concerns the cause of the conversion of glycogen into dextrose.

THE CAUSE OF THE GLYCOGENOLYSIS

It has been known for long that the liver tissue contains a diastatic or glycogenolytic ferment. This ferment, which we may call glycogenase,[12] is contained in fairly active form in extracts of blood-free liver, the most satisfactory extract in this regard being that prepared by the well-known Buchner process. It is precipitable in an active state by alcohol, although prolonged contact with this reagent seems to cause a deterioration in its strength. It is extremely difficult to make accurate quantitative estimations of the amount of glycogenase in liver or any other tissue, but, in so far as such estimations have been made, there is no indication that it is any larger in amount sometime after death when post-mortem glycogenolysis is very active, than it is in a liver immediately after death. In the same way, no increase in the amount of glycogenase in the liver seems to occur as a result of those conditions which in the intact animal cause glycosuria.

This statement does not at first sight appear to be in accord with the results recorded by Bang, Lungdahl and

Bohm[13] to the effect that in incubated samples of minced (blood-free) liver of the rabbit there is more rapid glycogenolysis in a given time when, prior to death, there exists some experimental condition causing glycosuria. It is evident, however, that Bang's results instead of indicating an actual increase of glycogenase might be explained as due to influences affecting the inhibitory mechanism. Evidently, then, the production of dextrose by the liver, either ante-mortem or post-mortem is due, not to variable amounts of glycogenase, but to variations in the activity of the inhibitory mechanism which holds it in control.

Glycogenase is by no means confined to the liver tissue; it is present, in at least as great amount, in blood and to a variable degree, apart from the blood which they contain, in the kidneys, muscles, intestines, spleen, etc. The fact that as much, if not more, of it is present in blood as in the liver, as well as the other facts regarding its distribution, indicates that there is no relationship between the amounts of glycogen and of glycogenase in the animal body. Here again, is evidence that it is not the presence or absence of the ferment which determines whether glycogenolysis shall occur, but rather some controlling or inhibitory agency.

The same facts regarding the distribution of glycogenase would further suggest the existence of some definite site for its production. Since of all extracts those of the pancreas exhibit by many times the strongest glycogenolytic activity, it has naturally been thought that this gland is the source of the ferment. Should this be the case, there are two paths by which the glycogenase might gain the general circulation—the blood and the lymph. In the former case, we should expect to find glycogenase present in greater concentration in the blood of the pancreatic veins than in blood from the carotid artery. Such, however, is not the case, for both during ordinary anesthesia and when the nervous system is being stimulated in such a way as to produce hyperglycogenolysis, the amounts of glycogenase in the systemic blood and in that of the pancreatic veins are identical. It is therefore impossible to demonstrate any actual secretion of this ferment by the pancreas into the blood probably because of the great volume of blood. It may be, however, that the remarkable strength of the pancreatic extract is on account of the diastase which would otherwise have been contained in the pancreatic juice

The large amount of glycogenase in blood as compared with other tissues explains why the glycogen disappears with greater rapidity from the liver after death when the organ is left intact and full of blood than when, just immediately after death, the blood is washed out of it. The much more rapid glycogenolysis which occurs in a mixture of liver and blood-free liver tissue has naturally suggested the possibility that there might be something in the blood exercising an activating influence on the hepatic ferment. No evidence of such an activation can, however, be obtained, the greater glycogenolysis in the mixture of blood and liver being merely an additive function of the ferments present in each.

Regarding the nature of the mechanism by which glycogenolysis is inhibited or held in abeyance during life, we are almost entirely in the dark. In considering this question it has, however, to be borne in mind that the glycogenolysis produced by glycogenase takes place within the hepatic cell; it is an intracellular reaction and consequently is regulated by the vitality of the cell. In other words, the intracellular glycogenase is prevented from acting on the glycogen during life by forces which are dependent on the vitality of the protoplasm. On the death of the cell, therefore, glycogenolysis sets in. This function of the protoplasm is under control of the nervous system as is illustrated in the various forms of experimental glycosuria about to be described. It is of interest to note that section of all the hepatic nerves does not in itself cause any change in the amount of dextrose in the blood.[14]

MECHANISM OF GLYCOGENOLYSIS

We are now in a position to consider a little more fully the various conditions which may bring about glycogenolysis in the liver during life. These, as already mentioned, are the conditions which cause experimental glycosuria. Besides stimulation of certain portions of the nervous system and asphyxia, there are many drugs which have this effect, but since the exact mechanism by which most of these act has not yet been fully worked out, it would profit us but little in the present connection to consider them and we will rather confine our attention to the so-called nervous and asphyxial glycosurias.

The reflex arc through which the nervous control of the glycogenic function is effected has its center located in the fourth ventricle. Mechanical stimulation in this location in rabbits, as by puncturing, is soon followed by the appearance of a large amount of dextrose in the urine, dependent on great increase in the reducing substance in the blood. The glycosuria disappears when all the glycogen in the liver has been used up and it fails to appear when, prior to the puncture, the liver has been rendered glycogen-free by starvation or in some other way.[5, 15] The efferent path from this center to the liver is by way of the cervical portion of the spinal cord and the great splanchnic nerves.[7] The actual existence of these fibers in this portion of the cord has, however, never been demonstrated, for electrical stimulation here so interferes with the respiratory movements as to create a condition of partial asphyxia which in itself leads to hyperglycemia, and when this asphyxia is prevented by delivering a constant stream of pure oxygen into the bronchi, then stimulation of the cord does not cause an increase in the reducing power of the blood.[7, 14] It is possible that the great fall in blood-pressure or the spinal shock may be responsible for this negative result. In the great splanchnic nerves, on the contrary, it is a very easy matter to demonstrate the presence of the fibers;[16] indeed, in my experience, there is no more certain way of bringing about a rise in the reducing power of the blood than by stimulation of these nerves. The nerve fibers involved must of course descend by the cervical portion of the spinal cord, and they leave the cord by the spinal roots in the lower dorsal region.[17]

There must also be afferent influences carried to this glycogenic center and it is believed that these are most plentiful in the vagus nerve, but here again the experimental evidence is faulty on account of the fact that electrical stimulation of these nerves affects the respiratory movements and thereby tends to an asphyxial condition. Indeed, I have so far been unable to cause any increase in the reducing power of the blood by stimulation of the vagus nerves, when, by delivering pure oxygen into the bronchi, I have excluded the possibility of asphyxia.

Splanchnic glycosuria is, I consider, an experimental condition worthy thorough investigation, for in this particular instance, in contrast to practically every other form of experimental glycosuria, we have a simple uncomplicated problem; that is, we are studying the effect on a definite function of a gland produced by stimulation of its nerve. Although, as already explained, the excessive production of dextrose by the liver is not to be considered as the immediate cause of diabetes, yet in every variety of this condition it is the cause of the hyperglycemia in the early stages, and even in the later stages the glycogenic function on which it depends can be shown to be abnormal.

NERVOUS CONTROL OF GLYCOGENIC FUNCTION

In connection with this comparatively simple condition of splanchnic glycogenolysis there are several questions concerning the nervous control of the glycogenic function which are susceptible of tolerably exact investigation. The most important of these concerns the exact nature of the nervous control. Three possibilities exist:

1. The nerve may control the production of the glycogenolytic ferment just as the secretory nerve fibers in the chordi tympani control the secretion of the submaxillary gland.
2. The nerve fibers may have no direct influence on the amount of glycogenolytic ferment, but may exercise a control on those conditions which retard or inhibit its activity.
3. The vasoconstriction produced in the liver by stimulation of the nerve may lead to an asphyxial or anemic condition of the hepatic cells which then permits glycogenolysis to proceed.

In considering these hypotheses it is convenient, first of all, to see whether there is any evidence in favor of the last one. I have attempted to furnish this evidence by making comparison of the rate of glycogenolysis in the liver deprived of its blood-supply (by connecting the portal vein with the vena cava and in some cases also ligating the hepatic artery) with and without stimulation of the splanchnic nerves. In such a case a greater glycogenolysis could not be attributed to changes in blood-supply, and would therefore indicate direct action on the liver cell. Although my first few results in this direction showed a distinctly greater glycogenolysis when the nerve was stimulated, I have been led, by more extended studies on post-mortem glycogenolysis, to conclude that the marked irregularities in the time of onset and in the velocity of this process make it dangerous to depend on such differences as we found for a solution of the problem. It must be remembered that deprivation of its blood-supply in any case brings on a glycogenolysis in the liver which is probably as intense as it can be under *any* circumstances, so that it is scarcely to be expected that an increase in this, due to stimulation of the splanchnic nerve, could make itself felt.[11]

If it be the case that it is merely by its influence over the blood-vessels of the liver that the nervous system controls the glycogenic function, then surely changes in blood-supply produced in other ways should be expected to have a similar effect. The most important experiment in this connection is clamping of the portal vein. If this be done for short periods of time—two minutes or less—there is no evidence that sugar increases in amount in the blood of the general circulation; *i. e.*, no hyperglycemia becomes established, although the first blood issuing from the liver after the clamp is removed must of course have contained an excess of sugar. If the portal circulation be blocked for longer than about two minutes, however, then when it is reestablished, it continues to deliver an excess of dextrose into the systemic circulation so that a general hyperglycemia soon becomes established. Portal stasis for more than about two minutes evidently brings on hyperglycogenolysis which lasts at least long enough to cause hyperglycemia. Nor is it possible with certainty to perfuse the liver outside the body with defibrinated blood containing a normal percentage of sugar, without a rapid glycogenolysis occurring. I have repeatedly attempted this with the observance of every possible precaution against any cessation of the circulation (*i. e.*, starting the artificial circulation through a branch of the portal before the ante-mortem circulation has ceased, etc.), but in only one or two cases have I been able to render glycogenolysis any less active than it would have been in a dead liver. Evidently, then, the glycogenic function of the liver is affected by considerable changes in its portal blood-supply.

Less profound changes in the blood-supply, however, are without effect. Thus clamping of the hepatic artery and vasoconstriction in the splanchnic area produced by stimulation of the splanchnic nerves, after sectioning the hepatic branches so that there could be no direct action on the liver, do not cause hyperglycemia.[7]

I believe that it is highly improbable that the changes in blood-supply produced by stimulation of the splanchnic are of sufficient magnitude to excite glycogenolysis.

By exclusion, therefore, one is driven to conclude that the nervous influence must be either on the production of ferment or on the inhibiting mechanism.

Sufficient work has not as yet been done on this phase of the question to warrant any final decision as to which of these two modes of action is actually involved. But everything so far points to the latter as the more probable. Thus we have been unable to find that saline extracts of blood-free liver after stimulation of the splanchnic nerve are any stronger in glycogenase than those from resting liver. The histologic changes observed by Cavazzani in the liver cells before and after stimulation of the celiac plexus may be interpreted in terms of either hypothesis.[18]

EXPERIMENTAL DIABETES BY ASPHYXIA

A very common form of experimental diabetes is that produced by asphyxia. Clamping of the trachea and injection of curare are the means usually employed to bring about this condition. Many hypotheses have been offered of the mechanism thereby involved: that it is due to diminished oxidation of dextrose in the tissues, that it is due to asphyxial stimulation of the glycogenic center, and that it is due to the direct action of venous blood on the liver. The first of these is certainly untenable, for no hyperglycemia follows asphyxia when the liver is removed from the circulation by establishing the Eck fistula.[19] The hyperglycemia is unquestionably due to increased production of dextrose from the liver. The second hypothesis, *i. e.*, that there is asphyxial stimulation of the nerve-centers, is upheld by the observation that after sectioning all the hepatic branches of the celiac plexus hyperglycemia is no longer produced by clamping of the trachea.[17] Hyperglycemia, however, does occur after such isolation of the liver from the nervous system when the asphyxia is produced by injection of curare, indicating, therefore, that profound venosity of the blood may, besides acting on the nerve centers, also act directly on the hepatic cells.[20] This direct action of venous blood in stimulating glycogenolysis might be due either to the increased carbon dioxid content of such blood or to its deficiency in oxygen. By incubation experiments with mixtures of minced liver and blood we have shown that when the glycogenolysis occurring in two hours is compared in atmospheres of oxygen, carbon dioxid and hydrogen the greatest action occurs in an atmosphere of carbon dioxid, there being, however, no difference between that occurring in oxygen and hydrogen. The increased content of carbon dioxid in intensely venous blood may therefore stimulate hepatic glycogenolysis independently of the nervous system, but in ordinary conditions of asphyxia the glycogenolysis is a nervous one.

[18] Cavazzani, F.: Arch. f. d. ges. Physiol., 1894, lvii, 181.
[19] MacLeod: Am. Jour. of Physiol., 1909, xxii, 278.

It is well known that a slight degree of acidity favors the action of all diastatic ferments; the increase in carbonic acid in the blood acts in this regard as any other feeble acid would. This result led me to study the effect on the percentage of reducing substance in the blood of the systemic circulation of injection of small amounts of lactic acid into the blood of the portal vein. I did not, however, obtain any evidence of hyperglycemia, but I do not consider that the experiments are at all conclusive, for it is only with very slight degrees of acidity that diastatic action is accelerated; it is depressed by larger amounts. The amounts of acid injected, though in some cases quite small, were yet probably beyond the optimum.

It has been pointed out that the hyperglycemia following several experimental procedures is in many cases the result of a more or less marked asphyxia coincidentally produced. When oxygen is freely delivered into the alveoli, many of these experimental conditions no longer cause hyperglycemia. We have already referred to this matter in connection with the so-called reflex forms of nervous diabetes, and in that which follows stimulation of the spinal cord. Observations of the same nature have been made by Underhill in the glycosuria-producing effect of certain drugs such as nicotin, morphin, pyridin, anesthetics, etc.[21] It is probable that the free administration of oxygen prevents glycosuria in the cases by its accelerating the oxidation of lactic acid, etc. The free perflation of the pulmonary alveoli also removes carbon dioxid from the blood.

INTERNAL SECRETIONS

As a final group of experimental conditions which produce glycosuria, must be mentioned the secretions of certain ductless glands. Besides the pancreas, whose influence in this connection will be discussed separately in the symposium, we have to consider very briefly the adrenal and the thyroid. Injection of epinephrin, especially when it is made subcutaneously, is followed by glycosuria after a latent period which varies considerably in different animals. When the injections are made intravenously, very little glycosuria is produced. Repeated injection ultimately leads to disappearance of the glycosuria although the hyperglycemia persists. This immunity is probably due to diminished permeability of the kidney to sugar.[22] When the epinephrin injections are given to rabbits that have been starved or treated with strychnin so as to render the liver poor in glycogen, the glycosuria still occurs, and, curiously enough, more glycogen comes to be laid down in the liver.[23] Administration of epinephrin to starved dogs which are fully under the effect of phlorhizin does not cause any increase in the elimination of sugar.[24]

It is sometimes stated that the epinephrin causes glycosuria because it has an inhibitory action on the glycolytic or sugar-destroying influence of the internal secretion of the pancreas; it is supposed to hinder this to such a degree that dextrose accumulates in the blood.[25] There is, however, no experimental evidence in support of this hypothesis. It is more reasonable to explain the epinephrin action as being on the nerve control of the glycogenic function of the liver.[23] It is known that epinephrin owes many of its other physiologic activities to its stimulating effect on the sympathetic autonomic nervous system. It seems rational to conclude, therefore, that hyperglycogenolysis which it induces when given to well-fed animals and the evident derangement of hepatic functions which, as above noted, follows its administration to starved animals, is due to the same cause. In this connection, it is important to note that it is only when the dose of epinephrin is sufficient to cause a rise in blood-pressure that it produces glycosuria.[27]

The parathyroid and probably also the thyroid glands stand in some relationship to carbohydrate metabolism; thus excision of three of the four parathyroids in dogs greatly lowers the tolerance of the animal for sugar and complete thyreoparathyroidectomy, besides causing tetany, etc., causes also glycosuria.[28] Some observers believe that the thyroid glands have an opposite influence to that of the parathyroids in their effect on carbohydrate metabolism.[29] These influences of the thyroid and parathyroid glands have been noted in clinical practice. In hyperthyroidism (exophthalmic goiter) if glycosuria is not present it is readily induced by feeding with sugars; in hypothyroidism (myxedema) glycosuria is practically never observed even when large amounts of sugar are taken.

In explaining these influences of the thyroid and parathyroid on carbohydrate metabolism, it is customary to assume that it can be only on the glycolytic or sugar-destroying action of the pancreas.[29, 30] Indeed, this influence of the pancreas is frequently assumed to be the only function which can be abnormal in diabetes, but there is no justification for this belief, and until there is why should we bemuddle the situation by assuming that the other ductless glands retard or increase its action?

CONCLUSION

I would conclude by again urging that in the utilization of carbohydrates in the animal body the glycogenic function of the liver is at least as important as the glycolytic action in the tissues, and since there is plenty of evidence that this glycogenic function is easily deranged so as to cause diabetes, it should be more carefully investigated as to its participation in the cause of those forms of diabetes which at first sight may seem to be quite independent of it

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS LUSK,* MACLEOD, PRATT, WOODYATT AND WALLACE, CONSTITUTING A SYMPOSIUM ON DIABETES

Dr George C Smith, Boston I think we must consider that a functional glycosuria is distinct from the organic glycosuria that we have been discussing to day These organic glycosurias are incurable In other words, the people who contract that form of diabetes due to pancreatic disease under the age of 20 die, no matter what we do for them, dietetically or with drugs The form of diabetes that occurs after symptoms of organic disease of the intestines is entirely different, also the form of diabetes that occurs in combination with obesity, which most of us have treated, coming on at the age of 40 to 60 years These are functional The more we increase the power of the patients to digest carbohydrates, the more quickly they get well They come to us with a history of disturbed digestion for a long time, and not only because of sugar in the urine Reduce the patient's fat by diet, and the sugar immediately disappears Consequently, we should treat the patients because of their inability to digest carbohydrates When their weight becomes normal, do not stop there but continue the reduction till you reach the point at which they can digest carbohydrates, then you will no longer find sugar in the urine I feel therefore, that the most important thing to day is to treat the class of glycosurias that we can cure It is, of course, very important to find the cause of the special form of diabetes before us

Dr J A Lichty, Pittsburg I am glad that Dr Lusk has taken the position which he has with reference to fat metabolism In some of these cases the fats are our main article of food, which allows us to keep up the proper caloric value of the diet, and if we should find that fats in themselves are converted into sugar it would make our care of these cases all the more discouraging I can refer to these papers only clinically, and shall therefore, discuss Dr Wallace's paper particularly I wish to add one or two points with reference to increasing the carbohydrate tolerance In the early part of my clinical experience with these cases, I directed most of my diabetic patients as ambulatory, that is, I allowed them to go about their business and take their usual physical exercise Within the last few years I have found by restricting the physical and mental exertion I could increase the carbohydrate tolerance I have had the patients rest in bed and in the open air very much as we at present treat tuberculous patients In severe cases in which the diet did not seem to free the urine from sugar such a course of treatment frequently accomplished the desired result

Dr Wallace mentioned in his paper that the less food the patient can get along with and maintain his weight, the better it is for him I find this experience very valuable in these rest cure cases Because of the limited exertion the patients need less food A few years ago I reviewed my cases of diabetes a hundred or more, with reference to the relation of gall bladder trouble and glycosuria In some 250 of gall bladder and duct diseases I found only two cases of glycosuria One would expect to find more, since we know the relation of pancreatic disturbance to glycosuria I have also in recent years taken up the Cammidge reaction in the urine in these cases and I have been rather gratified to be able to distinguish a certain class of cases in which the Cammidge reaction is usually found They are patients of rather mature age They are rather emaciated and their weight can not be easily increased, the amount of sugar in the urine is small, and they find very little inconvenience from their condition In the young, thin patients I have never found the Cammidge reaction I have also had experience with several very interesting cases of diabetes associated with pulmonary tuberculosis. They were usually patients beyond the middle time of life, and belong to the fat, old type In several I ignored the diabetic condition and fed them as I would a patient with pulmonary tuberculosis They all promptly lost weight and developed a rather serious condition As soon as I placed them on a carbohydrate free diet, even though the caloric value was lower than my former diet, they increased in weight and their condition improved satisfactorily

Dr J P Matthews, Carlinville, Ill In my work, I have made a special study of gout and rheumatism In looking over the literature of these, I found that the idea is that gout and rheumatism are due to a faulty metabolism of the nitrogenous products of our diet In the oxidation of these nitrogenous products, there is a formation of uric acid and of urea If urea is not formed by a process of burning up or oxidation, we have these end products that are a direct cause of gout Now why could not this reasoning be applied to the subject of diabetes? Why could we not say that there is a suboxidation of the carbohydrates, causing acetonuria, or, as I think the technical term is, the formation of a leukomain or of a poisonous product due to the suboxidation of the carbohydrates? Why cannot a reasoning be applied to diabetes analogous to that which we have applied to gout?

Dr Graham Lusk, New York I do not wish to have Dr. Woodyatt's excellent paper go without discussion In my laboratory, Dr Ringer and I have lately seen that glycocoll, when ingested in phlorhizin glycosuria is converted into sugar, perhaps through glycollic acid, and afterwards glycolaldehyd. We have also found that glyceric acid can be converted into sugar Possibly glycolaldehyd and glycericaldehyd as given by Dr Woodyatt were converted into sugar If this sugar had been oxidized it might have reduced the quantity of oxybutyric acid in the urine These experiments might be properly controlled by comparing the action of glycolaldehyd with that of a similar quantity of dextrose itself to see their relative influence on the diabetic condition One substance may be named in this connection that might be of possible benefit, and that is pyroracemic acid The diabetic may convert lactic acid into dextrose and this is therefore useless The corresponding ketone pyroracemic acid might possibly be a substance that could be directly burned by the cells in the place of dextrose If we can by scientific research make such a substitution we shall arrive at a cure for diabetes

Dr J J R MacLeod, Cleveland, O I should like to sum up the position with regard to the study of diabetes I believe that it is wisest to use the most conservative treatment I think that the conclusions drawn from the recent work done in experimental diabetes have rested on two faulty assumptions One is that the conversion of glycogen into sugar by the liver is a function variable in amount, and the other is that a large number of the recently discovered instances of this form of diabetes are due to deficient glycolysis What I should like to bring up is the fact that for neither of these two contentions is there much evidence The contention that there is a substance in the liver which is susceptible of being secreted in varying amount, there is not a particle of evidence to support This substance, which we call glycogenase, occurs in rather small amount in the liver In the case of the dog, there are large quantities of this substance in the blood, and probably relatively not more than 25 per cent as much in the liver This being the case, it seems to me that the assumption of the existence of variable amounts is probably faulty and misleading

Dr R T Woodyatt, Chicago In response to Dr Lusk's remarks concerning the possibility of getting some antiketogenic substance that will be incapable of being converted into glucose, it seems to me barely possible that such a substance may never be found, for the reason that the conversion of one chemical compound into another is coming more and more to be interpreted as dependent on preliminary chemical dissociation If lactic acid can go over into sugar it means that prior to the formation of the sugar the lactic acid must have been in an intermediate, active or dissociated state, susceptible either of transformations, union with other similar molecules or of oxidation Since the same state is necessary for oxidation as for condensation, it is possible that to let a substance be dissociated may insure its condensation as well as its oxidation. Therefore, I can conceive that to pursue the search for an antiketogenic substance that will oxidize and not be built up into sugar may be futile. As to the question whether glycerin aldehyd was turned into glucose before oxidizing, I cannot say definitely that it was not, but in the same patient to whom we gave it, larger percentages of sugar were obtained in the urine when glucose itself was given than when glycerin aldehyd was administered. The condition of the patient varied, however, from time to time, in spite of all precautions. The possibility suggested by Dr. Lusk is there, and it would be dogmatic to say that it could not occur. The second chart, in which the glycerin aldehyd was given under conditions that hypothetically favored its condensation into glucose, shows an almost quantitative excretion of the triose as glucose—which is evidence (partly hypothetical, to be sure, but significant) that when glycerin aldehyd did go over into glucose, it then fell out of the body as such.

DEHYDRATION BY DIETETIC MEASURES

AN INTERPRETATION OF THE KARELL, OERTEL AND WIDAL TREATMENT OF CIRCULATORY AND RENAL DISEASES

A. MAGNUS-LEVY, M.D.
BERLIN

The German word, *Schonungstherapie,* being untranslatable, I have adopted as the nearest English equivalent for it the expression "protective therapy" or "sparing therapy." This means to allow an organ to rest and to strengthen it by temporarily making as little claim on its functions as possible. In contrast to *Schonungstherapie* or "protective therapy" is *Uebungstherapie*, a treatment by which an organ is stimulated to work. These are the ideas and terms first employed by the German physician Albin Hoffmann. What they mean will be readily appreciated when the different forms of therapeutics employed in the treatment of the diseases of the heart are considered. Confining an arteriosclerotic patient to his bed is *Schonungstherapie*—protective treatment. If on the other hand walking and climbing are prescribed for him, which of course must be definitely limited, that would be employing the *Uebungstherapie*—treatment by exercise. Hoffmann has most wisely discussed the problems of general therapeutics from these two standpoints: the treatment which protects and spares an organ, and the treatment by which an organ is stimulated to work or perform its functions. Indeed these two ideas are applicable to the therapeutics of the impaired functions of all organs.

The dietetic treatment of circulatory disorders is essentially one form of protective therapy. The names of three authors demand especial attention in this connection; those of Karell, Oertel and Widal. The best and most widely employed methods of treatment are associated with their names, and these also indicate distinct epochs in the development of therapeutics. There are wide differences in the practical standpoints and underlying theoretical considerations adopted by these authors. The essential feature of the Karell treatment is the exclusive use of milk in relatively small quantities at definitely stated intervals. The idea underlying Oertel's method is a great reduction in the quantity of fluid ingested. The Widal treatment on the other hand, consists in excluding sodium chlorid as much as possible from the food, which in other respects is the ordinary mixed diet

Karell was purely an empiricist; he described his procedure as a milk treatment, *la cure de lait,* and stipulated that its rigid enforcement required six weeks. He began in the first week by giving small quantities of milk, from 60 to 200 c.c., four times a day at intervals of four hours. He then increased these quantities in the course of the second and third week, and finally allowed at the end of the fourth week the addition of small quantities of foods intended to stimulate the appetite, such as salt herring and salt bread, but without any other concessions. Only after the lapse of five to six weeks did he allow the patient daily a single real meal, besides which, three times a day, milk in various forms was to be taken. Karell considered that the chief field for his method lay in the treatment of all sorts of circulatory and renal disorders, especially when combined with edema. But he obtained good results in other conditions as well; for example, in the most varied diseases of the gastro-intestinal tract, in neuralgias, and in functional nervous affections. Karell was an excellent practitioner and paid but little attention to theories. He even deprecated any such attitude on his own part and simply said he believed that the results obtained were referable to one of the components of the milk or to the particularly suitable combination of all its components. It did not occur to him that it was chiefly negative qualities that produced the results; that is, the reduction in the total amount of solids and fluids given, and that the treatment was really an especially marked form of protective treatment.

Oertel started out from a theoretical basis. He assumed, with a certain amount of justice, that after the development of a circulatory disorder it was chiefly the increased amount of fluid in the body that made a return to normal conditions difficult. He regarded the daily ingestion of large amounts of fluid as contributing greatly to the work imposed on the heart, and endeavored to correct this factor. The field of his activity explains why he came to devote especial attention to the amount of fluid taken in, for Munich, the city in which he worked, is the city in which the consumption of beer is greatest. He began his investigations and his treatment by allowing his patients to continue their ordinary mode of life, but had them measure the amount of fluid taken in and the quantity of urine voided.

In healthy people the latter usually is several hundred cubic centimeters less than the former, since water is given off also by the skin and lungs. If the amount of water taken in is reduced, in healthy individuals urinary excretion becomes almost correspondingly less; but in subjects suffering from circulatory disorders this decrease is very slight or does not occur at all. That is, by Oertel's plan of treatment an excess of water was removed from the body: circulation was relieved; the amount of circulating blood was reduced; and the restoration of normal conditions was favored.

Oertel assisted this principle of removing superfluous water not only by restricting the amount of fluids taken in but also by other measures, such as exercise, hot baths, etc. He investigated the effect of his treatment on the various forms of circulatory disorders, employing all the methods then available. Determinations of blood-pressure, hemoglobin, of the concentration of the blood, and its amount, appear prominently in his reports. In addition he also devoted much attention to nutrition in general. In obesity, the removal of water was combined with measures for reduction of the amount of body fat, a principle that he carried out in a more rational manner than did Ebstein. If the patients were emaciated he endeavored to produce an increase in their weight and so on. As far as the quantitative composition of the diet was concerned, he based his mode of procedure on the observations of Pettenkofer and Voit; that is to say, he had already adopted practically our modern point of view. But I might mention that his principle, the prescription of much protein in the food, is at variance with the restriction of fluid taken in, as I will point out later. When the disturbance of circulation was associated with edema he regarded the condition as lying outside of the scope of his specific treatment. This he considered as especially applicable in the moderate circulatory disturbances attending arteriosclerosis, cardiac weakness, and obesity.

Oertel must be regarded as the father of the scientific dietetic treatment of circulatory disorders as founded on theoretical considerations and the rational application. At present, we do not agree with many of his conceptions; but the principles on which his method was founded are still in many respects remarkable.

Science achieved the most admirable triumph when it recognized the significance of the relation of sodium chlorid to the circulation and the development of edema. It is to Widal that this conception is chiefly due. He started from theoretical considerations, and also from experiments at the bedside. After it had been established by various observations that sodium chlorid was poorly excreted by the diseased kidney, he and Strauss simultaneously hit on the idea that it was precisely the retention of this substance which was the crucial factor in the production of edema and that gave rise to its appearance. We are all familiar with the brilliant experiments by which Widal furnished irrefutable proof of this conception.

I know of few observations in the whole history of metabolic treatment that can be compared to this for simplicity, clearness, and ease of demonstration. It is a classic experiment. With this single experiment, the result of which has frequently been corroborated, the predominant part which sodium chlorid plays in the retention of water was definitely proved.

The important part played by this substance in the water content of the diseased body can also be demonstrated for the healthy individual. Permit me to make a few observations in this connection. The various organs possess a definite content of sodium chlorid which is much less than that of the blood. The muscles are poorest in sodium chlorid, containing only 0.1 per cent., while the connective tissue, with 0.3 to 0.4 per cent., is richest. According to my analyses the total amount of salt in the body of a healthy man may be estimated as 130 gm. Owing to the fact that we take in a considerable amount of table salt, about 15 to 20 gm. a day, the body always contains an excess of medium chlorid above the minimum. When a healthy person fasts absolutely or takes his ordinary diet without the addition of any salt, he gives up 10 to 20 gm. of sodium chlorid. At the same time, he loses 1 to 2 kilograms in weight, without, however, sacrificing protein and fat. He gives up 1.5 liters of fluid, i. e., lymph. If now 15 to 20 gm. a day of salt are added to the salt-free diet, the healthy body does not during the first days excrete this amount completely, but retains the 15 to 20 gm. originally lost and at the same time corresponding quantities of water, 1 to 2 kilograms, are again stored up; in other words, the excess of sodium chlorid which is retained by the body on a normal diet and under normal conditions does not contribute to an increased concentration of the juices in this substance, but demands its own amount of water for solution, and in this way augments the quantity of fluid circulating in the body.

This fact having been established, Oertel's conception of restriction in the ingestion of fluid must be subordinated to the task of reducing the sodium chlorid. Whenever this is cut down, thirst becomes less and the amount of water taken is decreased in the natural course of events, without imposing on the patients the restriction of fluids.

In general it may be said that the salt-free treatment has only seldom been carried out in its most radical form, as it had been applied by Widal in his famous experiment. This is due to several facts; in the first place to the lack of persistence of physicians and patient. While the principle of the salt-free diet appears simple enough to apply, practically it requires thorough knowledge on the part of the physician and much energy on the part of the patient. The physician will always be more inclined to reduce the edema by stimulating renal activity with drugs rather than by the principle of protective therapy.

In a large number of cases the desired effect may be obtained with theocin, diuretin, digitalis, and so on. When this is not the case, the physician sometimes prescribes a salt-free diet, but promptly abandons this if it is not quickly effective. I should like to give an example of the amount of persistence and care required, and of what excellent results may then be obtained even in desperate cases. Last winter I found in the Friedrichshain Hospital two patients with severe parenchymatous nephritis and enormous edema. Both of these had been treated for five or six months with all sorts of remedies. Digitalis and digalen, theocin, diuretin, theobromin, potassium acetate, calomel, purgatives, hot packs, and scarification, had all been systematically resorted to in the course of half a year without leading to any permanent improvement. I now gave both patients a full mixed diet with meat, eggs, potatoes, vegetables, milk, bread, zwiebach, and fruit, without excluding any article of diet, but without the addition of the least traces of salt. The bread, zwiebach, and butter also were made without the addition of any salt. In the case of one patient, a boy of 14, the weight in the course of three weeks fell from 55 to 40 kilograms, but that of the other changed but little. My colleague, Stadelmann, who knew the patients of old, expressed the opinion that but little result was to be expected. In the next four weeks, however, the patient lost 30 kilograms in weight, and the last trace of his edema disappeared. During these four weeks he had excreted about 300 gm. of sodium chlorid. In the first three weeks the kidney had been only slightly permeable for the salt, and therefore but little water could be removed from the body. After the excretory power of the kidney had been spared (*geschont*) during the first weeks a period of greater activity followed which quickly brought about the complete removal of the edema. In such difficult and desperate cases not only persistency and stern determination are necessary, but also the strongest restriction of sodium chlorid. The patient received about 2 to 3 gm. of sodium chlorid a day in his food. If he had been treated a little more laxly and had been allowed even 5 to 6 gm. only, he would never have been freed from his edema.

The importance of this observation lies in two facts, namely, (1) that the salt-free diet had proved efficacious after all other therapeutic measures had failed; and (2) that it required fully seven weeks, in the first of which no distinct improvement seemed to be obtained.

The salt-free diet is most efficacious in parenchymatous nephritis. In this condition, in which the salt does not pass through the diseased kidney, its significance is perfectly evident, and the immediate therapeutic effect is most striking. But also in other forms of passive congestion, as in cardiac insufficiency and cirrhosis of the liver, the removal of salt from the food is often followed by surprising results. The mechanism is a little different from that in renal disease. In these conditions also a portion of the excess of sodium chlorid is retained in the body, not, it is true, because the excretory power of the kidney is primarily impaired, but because of the circulatory disorder. The salt is retained in the body together with corresponding quantities of water and other components, firstly in the blood-vessels, then either as edema under the skin, or as free fluid in the abdominal cavity. On cutting down the superfluous amount of salt taken in, the increase in the edema and the transudation ceases; this is followed by a certain equilibrium and the mechanics of the circulation become more favorable. Now the kidneys begin to secrete more actively, and this is followed by removal of the edema. In many forms of broken compensation it is possible to bring about normal conditions solely by removing an excess of sodium chlorid from the food, and without the assistance of any drugs. Even pleural exudates, whose development is less dependent on the quantity of sodium chlorid than that of congestive transudates, are sometimes favorably influenced by a salt-free diet.

Let us now ask, what is the relation between the different so called treatments of Karell, Oertel, and Widal, and how have we to judge them from a theoretical and from a practical standpoint? The Widal treatment has this in common with the strict milk cure of Karell, namely, the small amount of salt that is allowed the patient. Indeed, it was Widal who explained the well-known efficacy of the milk diet in nephritis by pointing out the small amount of salt present in this fluid. The salutary properties of milk depend, not on any positive characteristics, such as a peculiarity in the nature of the protein molecule, or a specific diuretic action of the milk-sugar, the fine subdivision of the fat in an emulsion, or on any particularly favorable mixture of these substances, but rather on a negative quality, its poverty in sodium chlorid. But even milk may be too rich in salt when given in large amount, and Widal has particularly emphasized this fact. Three liters of milk, which is the minimum amount necessary to maintain equilibrium, contain 5 gm. of sodium chlorid, and this is more than many a diseased kidney can excrete. A mixed diet of meat, eggs, bread, etc., like that referred to above, contains only 1.5 to 2 gm. of salt, if none has been added.

Whereas Karell's diet is similar to that of Widal in the low quantity of salt, it differs from that of Widal in the great reduction in the amount of all foodstuffs. During the first week the patient does not receive even a fifth of his requirements, and during the first five to six weeks the physiologic minimum is never reached. During this time the patient accordingly loses considerably in body protein and fat. The principle of Karell's treatment, therefore, consists in a reduction of the amount of all the foodstuffs allowed. In many cases it is more suitable than the Widal treatment, when this is carried out in the manner in which Widal performed his celebrated experiments. But it must not be overlooked that Widal in the above instance made use of a full dietary with 120 gm. of albumin, 170 gm. of carbohydrates, and 100 gm. of fat, in order to exclude all other factors, and to demonstrate the predominating rôle of sodium chlorid in water metabolism. In everyday practice not only is it unnecessary to carry out the treatment in this way, but it may even be injurious for the following reasons:

The ingestion of all organic foodstuffs increases the amount of fluid in the body in a manner similar to sodium chlorid, though not to quite so marked a degree and by a somewhat different mechanism. Fat appears to do this least, although for the purposes of its absorption a certain amount of bile, pancreatic juice, and intestinal juice is poured out, but as it does not dissolve in the body juices and is only emulsified by these its further transportation through the lymph and blood vessels does not require the assistance of water. The absorption of the carbohydrates demands considerable amounts of water, since the glucose content of the blood-serum rises only from 0.1 to 0.3 per cent. at the most. But as soon as the glucose molecule has been deposited as glycogen or has been oxidized, it makes no further demands on the water supply of the body. The water metabolism is most strongly influenced by the protein molecule. Not only does it require for its absorption and its transportation in the body relatively large amounts of water, but its end-products, urea, uric acid, etc., also demand considerable amounts of fluid for their excretion. It is for these reasons that the ingestion of much protein makes greater claims on the water-supply and on the organs of circulation, than do other foodstuffs.

The relationship of the protein metabolism and of sodium chlorid to the water metabolism is particularly well shown in diabetes insipidus. In the true forms of this affection it is impossible to control the increased excretion of urine by applying only Oertel's principle of restricting the ingestion of fluid, but thirst and the amount of urine excreted immediately become less when the amount of salt taken in is reduced from 20 to 5 gm. The same thing happens if the quantity of albumin is cut down from 120 gm. to 60. Instead of 40 gm. of urea produced under the former conditions, now only 20 are excreted and the quantity of urine may be diminished by several liters more. In a similar way the reduction of the amount of protein in the food is of benefit in all circulatory disorders, though the effect is not quite so noticeable as in diabetes insipidus. In each instance the work of the vascular system and of the kidney is lightened.

RECAPITULATION

To recapitulate, we are in possession of three methods of reducing the amount of body fluids, and, in this way, effecting the dehydration of the body, in the first place, by lessening the amount of water ingested (Oertel's treatment), in the second place, by the reduction of the sodium chlorid taken in (the cure of Widal); and in the third place the use of a restricted dietary, especially poor in protein (Karell's cure).

Besides Oertel, the somewhat unreliable Schweninger and the layman Schroth, Von Noorden has laid emphasis on the reduction of the fluid intake. Von Noorden found this measure particularly efficacious in the polyuria of contracted kidney and in advanced arteriosclerosis. The reduction of the fluid taken in from 3 or 4 liters to 1.5 to 2 liters, was followed by a great improvement in the condition of the patients. In many instances the blood pressure fell 30 to 40 mm., the nocturnal polyuria became less, and the nocturnal attacks of angina and asthma ceased, especially when no fluids were taken in the course of the evening. Von Noorden has demonstrated that 1.5 liters of urinary water suffice in cases of contracted kidney for the removal of all the products of metabolism, and that there is no danger of uremia under these conditions. In such cases in which a great excess of water had previously been taken the effect of reducing its intake is very pronounced, and is readily explicable on theoretical grounds.

It is but rarely, however, that the effect of reducing the amount of water intake depends on this factor alone. As soon as this measure is enforced with some degree of strictness, so that the patient receives less than 1 liter of fluid per day, in most cases he will find it impossible to eat as much as before. This explains the well-recognized value of reducing the consumption of fluids in the various obesity treatments, as in that of Oertel, in that of Schweninger, etc. Schweninger allowed his patients to drink freely between meals, but forbade drinking at meals. The importance of this prescription evidently lies in the fact that, by forbidding drinking at meals the amount of food taken is reduced. The same principle is to be found in the thirst cure of the layman Schroth, in which a further loss of appettite is caused by the monotony of the diet. But I wish to emphasize especially that, contrary to the views of the laity and to the erroneous theoretical considerations of Oertel, Schweninger, etc., lessening the amount of water does not increase the oxidation of fat. This happens only in the most extreme forms of thirst cure, after the method of Schroth, when fever, abnormal decomposition of proteins and other dangerous complications occur. On the contrary, it is possible with proper management to carry out obesity cures not only without cutting down the water ingestion, but even by giving large amounts of fluid, as has been suggested recently by G. Rosenfeld. This clinician favors filling the stomach and intestine as much as possible with water, in order to control the subjective sensation of hunger. It is possible that these large amounts of water may stimulate metabolism and the oxidation of fat. That this is true has apparently been demonstrated by Heyl.

I believe that the effect of reducing the amount of fluid alone is seldom dependent on this factor only, as for example in chronic interstitial nephritis. In general the measure acts indirectly by inducing the patient to become unconsciously more abstemious in eating and usually to avoid strongly salted food which increases thirst.

The reduction of sodium chlorid is indicated especially in the edema of parenchymatous nephritis, but it is also useful in combating some of the symptoms of contracted kidney, such as headache, uremic asthma, angina pectoris, and pulmonary edema. Diabetes insipidus and cirrhosis of the liver also require mention in this connection. It seems to me that it is wrong to allow patients who have been relieved of dropsy and other chief symptoms by a Widal treatment to return to their ordinary salty diet. Although the excretory capacity of the diseased kidney undergoes considerable improvement after a period of functional rest, so that it may at times be rendered capable of excreting 5 to 10 gm. of sodium chlorid instead of only 1 to 2 gm., it would be wrong to impose on it a normal amount of work. In cirrhosis of the liver I also attach much importance to a long-continued reduction in the salt intake. While the reaccumulation of ascites after aspiration does not depend exclusively on an excess of ingested sodium chlorid, this is none the less an important factor. I would call attention to Achard's instructive case of cirrhosis of the liver in which he succeeded in removing the ascites five different times by enforcing a salt-free diet. Patients with diabetes insipidus must permanently refrain from a salty diet, since it is impossible to improve the capacity of the diseased kidney for excreting concentrated urine.

I now come to the third point, the reduction of the protein intake. I have already indicated that Oertel's two principles of low water and high protein intake—he required up to 200 gm. of protein a day—are at variance with each other. His regulations date back to a time when the study of metabolism was chiefly concerned with the behavior of the proteins, and the maintenance of the nitrogen equilibrium was held to be the most important consideration from a therapeutic standpoint. At that time it was believed that the bodily weakness which sometimes appeared in rapid obesity cures was due to a loss of muscle protein particularly by affecting the heart. But I should like to call attention to the fact that a loss of albumin content and of muscle volume by no means invariably leads to impairment of the capacity for bodily work. (This is plainly evident when persons unused to bodily exercise take up some mild form of sport, especially moderate mountain climbing. In spite of the fact that there is at first a prompt loss, both of fat and of muscle tissue, the cardiac and body musculature improve greatly in functional capacity). Felix Hirschfeld was the first to oppose the theory that a patient with heart disease should be protected against further weakness by abundant food, particularly by the administration of large amounts of protein. His firm stand in this respect was well grounded. He showed that reducing the amount of water alone did not suffice to restore compensation, but that it was necessary at the same time greatly to cut down the food taken as a whole. His opposition to Oertel's teaching is entirely correct on this point, and this has been demonstrated by many clinical observations.

In addition to its immediate effect on water circulation, a diet poor in proteins probably acts favorably in other directions also. Chittenden has called attention to its advantages in healthy persons, without, however, being able to explain this result in detail. In some diseases we can plainly demonstrate the harmfulness of a diet rich in protein, as, for example, in diabetes mellitus. In this condition it impairs the tolerance for carbohydrates, sometimes to a most pronounced degree. In opposition to Oertel's opinion, reduction in the ingestion of protein is particularly to be recommended not only in cases of broken compensation, but also in the case of cardiac patients who were previously high livers and exhibit a certain degree of plethora. It is also particularly indicated in the later stages of chronic interstitial nephritis, when uremic manifestations of greater or less severity appear. These are due largely to the retention of nitrogenous end-products of metabolism. I do not wish by any means to go to extremes and recommend always a minimum of protein in such cases, but I do consider it more advantageous for a nephritic in his last years to sacrifice a few kilograms of weight on a scanty protein diet and feel fairly well, rather than to maintain his weight at the expense of chronic uremic manifestations.

What shall be our attitude in regard to these forms of treatment in an individual case? I think that it is best if we first attempt to carry out each one of the three treatments exactly according to the directions of Karell, Oertel and Widal, in suitable cases. Only in this way can we form a correct opinion of their principles and their utility. Each one of these principles of water removal is attended by certain difficulties in its practical application, and these can best be overcome at first by strict adherence to the rules laid down by the three authors. When we have done this a few times we shall be able to deviate from the regulations and modify them in detail. Then we shall be able to determine whether it is more advantageous in a given case to secure relief for the circulation by restricting the intake of water, by a salt-free diet, or by reducing the amount of albuminous food, which as a matter of fact reduces itself to forbidding or restricting the consumption of meat but sometimes also of milk. In the Karell treatment I consider it particularly important to adhere carefully to the four-hour intervals between the separate portions of milk allowed the patient. It is frequently necessary to use skim milk, as Karell advises, in order to accustom the stomach of the patient to the monotony of the milk diet.

The salt-free diet of Widal is theoretically easy to administer, but one is apt to encounter the opposition or lack of comprehension of the cook. It is hardly necessary to forbid any article of food if only it is given in its natural condition and without any addition of salt on the part of the human hand. Of the fresh articles of food only salt-water fish are to be excluded. The butter should be unsalted and the bread must be specially baked without salt. Of course all forms of preserved meat and fish as well as cheese must be avoided, for these contain a great deal of salt. Milk also can be permitted only in small amounts, for it contains about 2 gm. of sodium chlorid per liter. By giving chiefly cereals, oatmeal, rice, hominy, custards, jellies, puddings, fruit, and desserts, the lack of salt is made more endurable to the patient.

If we wish to allow a patient a certain amount of salt after he has been for some time on a salt-free diet, we should not content ourselves with the general direction that he shall use moderation in salting his food, but prescribe a definite amount that is allowed. The conditions are comparable to those in diabetes mellitus, in which instance it is necessary to give the patient the most precise directions. I, myself, manage in this way. I have the food prepared without salt just as during the strictest period; then I give the patient small, accurately weighed quantities of salt, say 2, 4, or even 6 gm., and permit him to add this salt to his food in whatever way he wishes during the twenty-four hours.

The dietetic measures are just as important in the treatment of circulatory disorders and renal diseases as is the dietetic treatment of the glycosurias. I should feel much gratified if what I have said should enable any to gain a deeper comprehension of the principles involved and to apply them more widely than before.

Berlin, N. W., Karl-Strasse 5b.

Absence of Puncta Lachrymalia (Bilateral).—A child, aged 10, suffered from epiphora since birth. An attempt was made to pick up the opening in the canaliculus in the left lower lid, without success. The right gland was partially removed through an incision at the outer margin of the upper lid. Not succeeding, both lachrymal glands were removed through the conjunctiva at outer angle of the upper lid.—L. Cole-Baker, *Proc. Roy. Soc. Med.*, July, 1910.

HOUSE QUARANTINE *

H. COHEN, M.D.
Assistant Chief of Bureau of Contagious Diseases, Department of Health
CHICAGO

It is hard to separate the causation of disease in from the influence which organized society exercise him. The relations are many and complex, acting divers ways, and not always with visible directne For one thing, if you think of it, the important fact of heredity in the causation of disease is, truly a broadly considered, a social factor. And when we mention environment, the other half of the entire etiologic circle, it is readily seen that that in particular depen on the social aggregate and its intelligence and activit in behalf of the preservation of health for its compos tion and complexion, for the power of doing good evil, for its influence on health and disease.

Man *probably suffered from certain diseases and acc* dents in his pre-social days, but that the greatest percentage of man's present ills is socially caused, directly or remotely, is a certainty. Whereas the above applies, more or less, to all diseases, it is particularly applicable to the contagious diseases. Seed, soil and the planting of the seed are the three requirements in the causation of contagious disease; man himself fulfills two of these; he offers the soil and acts as disseminator of the seed through the avenues of social intercourse.

It follows that the control of contagious disease is a proper and necessary function of organized society. The individual is now considered an asset of the state, which would suffer loss by his illness or death, even if the effects were limited to himself. How much greater the mischief and loss is to the community in the case of contagious disease, anyone can readily see. And the community owes each of its citizens protection against contagious disease as well as against fire, against robbery and murder.

THE QUARANTINE PROBLEM

When the prevention of disease first claimed public attention, when it first began to be the concern of organized government, it was readily seen that the gathering of health statistics was of prime importance. And so it is, if properly utilized. Health statistics should furnish a guide as to proper health measures and methods; it should indicate to us the preventable leaks to life and health; it should be an aid, and not an aim. By itself it will accomplish nothing. We must not stop with that. Advanced and aggressive attitude and action is urgently needed in the control of contagious diseases.

In house quarantine, we have an important measure in the safeguarding of the well from the existing foci of infection. It is a truism to say that the essential features of the contagious diseases are their communicability, yet the fact needs emphasizing. There was a time when, owing to the lack of knowledge as to the cause, and by reason of the prevalence of superstition, epidemics of contagious diseases were attributed to visitations from heaven. Those times are, happily, passed. We now have a more exact knowledge of the cause of contagious diseases. We are now better able to cope with them because we more fully understand the actual determining cause, the various pathogenic bacteria, the contributing factors, and the means and [illegible] these germs are carried from the sick quarter lite we must make intelligent application of this me edge if we are to minimize these diseases. We in ve that persistent application of the principles of ti ntive medicine will ultimately lead to the almost ol eradication of contagious disease.

---

* Read in the Section on Preventive Me of the American Medical Association Session, held at St. Louis, Ju

w survey of the premises of the quarantine problem h s to the fore the following as the most salient:

irs The patient the only original source of infection.

2. The patient and contacts the most dangerous carriers neading infection.

3. Houses and objects such as bedding, clothing, toys, etc., harbor and give off infection.

How best to meet and circumvent the difficulties presented by these three factors is the crux of the quarantine question.

Before outlining the measures and methods here advocated and now in force in Chicago, let us dwell for a moment on conditions as they are with respect to the management of contagious disease and the many relations which it has to the public health. The statements here made are chiefly based on experiences in this work gained in Chicago. I am sure that they apply to a greater or lesser extent, to all larger towns and cities.

In our daily work we come in contact with people of all races and nations, people of all degrees of material welfare and educational status. We find the greatest disregard for the proper management of contagious disease, the greatest hindrances, due to the following causes:

1. The thraldom of inhumanizing poverty in which great numbers of the foreign-born population find themselves, with the woeful overcrowding attendant on it.

2. Ignorance and superstition—dense, miry and demoralizing—productive of a stupid disregard for all health regulations.

3. A peculiar nonchalance on the part of the semi-intelligent who think that they know it all and need not be taught how to properly care for a contagious case or themselves be subject to necessary restrictive measures.

4. The outright and outrageous assertion of self-interest against community interest on the part of some of the wealthy families and individuals in the community.

The following concrete instances elicited in a recent series of investigations to determine the exact mode of spread of contagious disease, will illustrate conditions as they are:

Series 1.—Diphtheria, six cases, two deaths. A child took sick with "sore throat." No physician was called in. The child grew worse and died. In the next house lived a relative of the above family whose daughter took sick several days later and also died. Four more cases rapidly developed in the surrounding families. Investigation showed that all had been visiting each other, had traded in the same neighborhood stores and otherwise neglected the most ordinary precautions.

Series 2.—Scarlet fever, four cases. First patient took sick on the eleventh of the month. The family in which the case occurred owned a small store, and through fear that the business might be interfered with, called no doctor. The case was not discovered until the fourth of the following month—nearly a month after it developed. Meanwhile the patient was out playing with other children, three of whom took the disease from her.

Series 3.—Scarlet fever, six cases. A boarder in a poor family returned from the hospital where he said he had a "sore throat" and a "breaking out." Eight days after his return the 19-year-old son of the family, who shared the same bed with the boarder, developed scarlet fever and two days later capable children of the same family came down with ead of three patients were removed to the hospital ed to seek another place. The house to impose on it a normal amou

was immediately disinfected. Within a week two more children came down with the disease.

Series 4.—A youngster who was delivering newspapers into a scarlet-fever-infected house, himself came down with scarlet fever. His playmate and companion who went around with him while delivering the newspapers, also took the disease.

Series 5.—A little girl convalescing from scarlet fever met her chum; the usual kissing and embracing ensued. Several days later the other little girl was stricken with scarlet fever.

The instances are innumerable, repeat themselves everywhere, and are well known to you. They go to show that the people are ignorant of the primary laws of contagious disease and of the danger that lurks in them. It proves that we have neither sense enough to protect ourselves, nor conscience enough to protect our neighbors. It indicates a degree of public lethargy toward the existence of preventable disease and death that harks back to the dark ages.

In another series of investigations to determine the source of infection of cases of diphtheria and scarlet fever reported during the period of a week, the following was learned from those whose direct connection with a previously existing case was definitely established.

1. Twenty cases were traced to the association with a patient in the immediate vicinity.

2. Ten cases were due to association at school with children in whom the disease was unrecognized.

3. Four cases were caused by contact at the playgrounds with children in whom the disease was mild or undeclared, or with convalescing patients.

4. Three cases were found to be the result of an unreported case.

5. Two cases owed their existence to previous cases in the family.

6. Many cases were attributed by the family to a "cold"—only a predisposing factor, if true. More likely, the first signs of the illness, particularly in diphtheria, were taken for a cold.

The lesson is the same no matter what superficial cause may be assigned. It is always association with a previous case, in one way or another.

In the poorer sections of the city, it used to be the usual thing to find mothers with diphtheria-sick children in their arms gossiping with neighboring women likewise with babies in their arms and with several older children clinging to their skirts. Tales of woe are exchanged, sympathies are extended, and disease is given in return. Children suffering from scarlet fever in the convalescent stage were almost always found outside when the weather permitted, with hands desquamating, neck perhaps swollen with suppurating glands, surrounded by a crowd of boys all gamboling on a vacant lot, all absorbing the insidious elements of contagion. Visiting and receiving callers during the quarantine period is quite the thing with certain classes of people. Allowing the inmates in contact with the patient, as well as the patient himself, to run loose on the streets and mingle with the well, is an almost universal practice.

When the people shall appreciate the enormity of the crime of throwing a burning fagot of contagion into a mass of disease-inflammable children, such practices as above will be no more. Then the burden of sickness, the host of innocently crippled children and the toll of death will be much less—very much less. That the danger of conditions as they exist has been theoretically recognized is attested by the laws and ordinances everywhere in existence, if not in force. In almost all cities there are adequate laws and ordinances which, if rigidly applied, would meet the problem. The fault lies with the lack of enforcement of the rules. The attempts at enforcement are spasmodic: It usually takes an epidemic to stir the people into apprehension and the authorities into action. Here, too, in the very field of preventive medicine, that famous "ounce of prevention," has not yet been pounded into consciousness and practice. As a rule, the entire problem of the care and handling of contagious disease, the proper observance of quarantine, is at present left to the good or ill will of the variously constituted communities with their different grades of intelligence, material environment, hygienic knowledge and moral sense.

The practical measures now in use in advanced communities do not adequately take care of the situation.

Placarding premises harboring a contagious disease neither keeps the inmates in nor does it keep visitors out. It is a good measure, but in itself not sufficient.

Initial inspection of cases reported, where in use, establishes a perfunctory quarantine, but does not and cannot maintain it.

Termination by disinfection after the patient and contacts have mingled with the public and spread contagion broadcast is like locking the stable after the horse is stolen.

The needs of the situation are for better laws where the laws are deficient; for action tending toward the rigid enforcement of quarantine by prompt reporting, placarding and establishment of quarantine of infected persons and premises.

The need—the greatest need—is for a stringent thorough-going personal inspection of quarantined premises and cases they hold every day, or at least every other day. The need is absolutely to keep the inmates in and the outsiders out during the quarantine period. Those ordered to live away from home must be made to stay away. The exclusion of those living on the premises in a different and properly separated part of the house, as prescribed, from the rooms occupied by the patient and attendant must be enforced at all times. The need is for supervision of the means of taking in supplies into the infected house and particularly the manner of removal of articles from the premises.

In brief, there is need for personal knowledge of each case, the respective district, its inhabitants and the conditions obtaining there; there is need for bringing this knowledge to bear on each and every phase of the contagious disease situation; there is need for a man to be constantly on the ground to study, observe, teach, watch, correct and enforce the observance of quarantine as above outlined.

THE ENFORCEMENT OF QUARANTINE IN CHICAGO

In the beginning of December, 1908, the contagious disease situation as pertains to scarlet fever and diphtheria, became threatening. Neighborhood epidemics were springing up in every section of the city. It was feared that the experience of 1907, when half of the entire city was enveloped in scarlet fever, would be repeated. One of the worst local outbreaks occurred in the south side of the city and originated from several cases of scarlet fever found in the "peeling" stage, in a parochial school.

From Dec. 15, 1908, to Jan. 26, 1909, thirty-six cases of scarlet fever were reported in rapid succession from an area comprising 144 city blocks. Conditions in other sections of the city were similar. I then proposed the quarantine plan now in force, of which the following are the outlines:

1. The city was to be districted, for purposes of adequate control, into more or less equal divisions, taking into account the extent of territory and the number and character of the population in the respective districts.

2. A quarantine officer and disinfector was to be stationed in each district.

3. It was to be this officer's duty to enforce the observance of quarantine, to have an intimate knowledge of every case and its environment, to hem it in and hedge it in so that it would not give rise to other cases, to know when it was ready for disinfection, and to disinfect same when ready.

4. He was to report daily as to the condition of his district, the number of current cases, the number of inspections, the number of disinfections, etc.

This plan was applied to the district above referred to. On Jan. 30, 1909, strict quarantine of all infected persons, premises and contacts, was instituted. House-to-house calls were made by our inspectors each day or every other day, as conditions required. Working members of the family in which contagious disease existed were compelled to stay away from the infected premises; those remaining on the premises were properly kept away from the patient and attendant. The delivery of milk and other supplies to the infected premises and the removal of the necessary waste were regulated in accordance with the quarantine regulations. Semipublic places, such as grocery stores, bakeries, meat markets, candy stores, etc., were warned against admitting any one from infected premises. Visitors were barred and excursions prohibited. Quarantine became a fact.

Where cases were ready for termination, patients and inmates, premises and belongings, were disinfected, and quarantine raised.

The results obtained were very gratifying, in spite of the newness of the task. In the next nineteen days, but one new case appeared, on February 2, and it is probable that the infection dated prior to the beginning of rigid enforcement of quarantine. On February 20 only twelve cases remained in the district.

This experiment was repeated and tried out in two other districts widely different in complexion and distantly separated. One of these was taken under control on February 24 with forty-eight cases of scarlet fever and diphtheria in it at the time. In a month the number of cases were forced down to nineteen, a reduction of nearly 60 per cent.

At the same time we quarantined another district with thirty-three cases in it. At the end of a month the number of cases current were fifteen, a reduction of over 54 per cent.

Following the above experiments and their results, the plan was put into operation over the entire city, and applied to all cases of diphtheria and scarlet fever. This plan will now be described in somewhat greater detail.

It is readily seen that absolute isolation of the patient is the keynote of the entire problem. Not all cases are similarly situated with respect to the immediate surroundings. Some of the cases are located in fine residences, others in flats, still others in hovels. All throughout it is a process of adaptation to environment and all throughout the essential of isolation is kept in mind.

The patient and attendant are put into one or two rooms at one end of the house or flat. This part of the house is separated from the other rooms in the house by having the intervening door locked and sealed, provided there is a separate entrance to them. They should also contain all the necessary household facilities such as water, toilet and cooking facilities. Here the patient and attendant, nurse or mother, as the case may be, are required to remain during the entire quarantine period. No one is allowed to enter their quarters except the attending physician and the health officer, when necessary for the purposes of control. The body and bed linens are to be disinfected before removed, the garbage and house sweepings are to be burned or disinfected, in fact, all the details of the hygiene of the sick-room are under surveillance of an officer of the health department.

Where such ideal conditions obtain, the workers of the family are allowed to go about their business without any interference, providing however, that at no time is there any direct or indirect contact between them and the patient or attendant. The part of the house which they occupy is, as said above, separated by a locked and sealed door from the patient's quarters. Where the bath-room, cooking and the other facilities of the house are in use by the patient, the workers must arrange for the use of these facilities elsewhere.

But ideal conditions are not found everywhere, as every one knows. In many cases the construction of the flat or house will not permit absolute isolation as above indicated; the family may occupy a four-room flat with only one outside entrance, where such arrangements as above outlined are manifestly impossible. Again there may be other children in the family and the people too poor to employ a nurse. It may be said that the greater the difficulties in the establishment of good quarantine, the greater the necessity for it. It is no dead subject; it is not cut and dried; it requires the exercise of sound hygienic principle, common sense and tact. Where the patient cannot be perfectly isolated, we insist that the working members of the family should live away from home while the case is in progress. If they remain at home, they are not allowed to continue at their occupations. These are essentials that we absolutely insist on.

We not only center our attention and efforts on the persons of the patient and the other members of the family, but we are, in this work, concerned with the innumerable details of human life in so far as they have a bearing on this problem. In flat buildings it frequently happens that there is one toilet for the use of two families living on the same floor. In such cases, the well family is instructed to arrange for toilet facilities elsewhere in the building, and the members of the family under quarantine are to use the nearest toilet.

Another important feature to which I want to call attention is the particular effort that is made to protect the other children in the same family where there is a case in existence from infection. From the health and humanitarian points of view, it makes no difference whether the second patient bears the same patronymic or not—whether it is Smith or Jones. We are, in a way, more responsible for a second or third case in the same family, because we ought to have anticipated and prevented it. In diphtheria, the problem is partially solved by immunization, but in scarlet fever nothing short of removal or rigid separation of the well from the sick in the family proper will save the susceptible.

This is not fully recognized. We owe protection only not to others outside of the family, but also to the members of the afflicted family. To this end mothers are especially warned to beware of the dangers of combining the duties of nurse and housekeeper where there are other children in the family. The families afflicted with contagious disease are guided and helped through the trying period of the illness in every way possible.

We aim to do the work in a scientific and sympathetic way. While it frequently becomes necessary to be insistent and stern in order to protect the public health, no undue intrusion on the rights of the individual is practiced.

We recognize that the best results can be obtained by securing the good will and cooperation of those with whom our task lies. We try to make them conscious of the fact that they owe a duty to the community; to make them see their self-interest in the light of the community interest.

The correlative factors in this work, operating for or against it are the following:

1. Economic conditions.
2. Education.
3. Hospitalization.
4. Policing.

Economic conditions, poverty and its congener, ignorance, are by far our greatest opponents in this work. Rigid quarantine no doubt works a hardship on many poor families; it calls for a sacrifice of an altruistic character that many do not understand.

Education is our greatest ally. To bring knowledge to the ignorant and awaken a sense of duty in the careless is the first step. In a task of this kind, we can look for the full fruition of our work only when the poor and ignorant better understand their own interests in these matters and the well-to-do and well-informed have been sufficiently impressed with the necessity of giving thought to the interests of others. In this campaign of education the family physician occupies an important position. His efforts and influence should be freely given to the cause of health.

Hospitalization of contagious cases is, of course, the surest means of securing isolation of the patient. It is, unfortunately, impossible to always do that at present, both on account of the lack of adequate hospitalization facilities for contagious cases, and for the reason of an opposed public opinion to such a measure as universal hospitalization. It has, however, a two-fold bearing on the quarantine situation.

On the one hand, the rigid quarantine regulations induce many families to send the patients to the hospital; on the other hand, the fear of having the patient forcibly removed to the hospital in case quarantine regulations are violated makes them live up to these regulations.

It frequently becomes necessary to police the quarantined premises, when the people are careless and refractory and the danger of the spread of the disease is considerable. This always has a salutary effect. It convinces them that the department means business and they readily fall into line and are willing to learn and observe the regulations.

This system of quarantine enforcement in Chicago, as far as diphtheria and scarlet fever are concerned, has been in existence a year now. One year is a very short period for such an undertaking. The difficulties were many, and the means at hand, as far as money and men are concerned, were inadequate for the task in hand. Yet a considerable improvement in conditions was achieved, both as to the educational influence it had on the public, resulting in a changed attitude towards necessary health measures and a broader knowledge of the same, and also in its direct bearing on the morbidity of scarlet fever and diphtheria. This system of quarantine regulation and surveillance was inaugurated in May, 1909. It did not get well under way until about September. Here is a comparison of the number of cases reported during the twelve months preceding quarantine enforcement, with that following it:

ment has been to place around the mask a rubber covering which confines the vapor and assists in making the anesthetic more manageable.

If one ounce of the oil of bergamot or terpineol is placed with 3 ounces of water in the hot-water bottle, the odor of ether or chloroform will be so disguised that the patient will be unable to distinguish when the anesthetic is turned on, and consequently no resistance or asphyxial symptoms present themselves in going under the anesthetic. Then again, it is much pleasanter for the surgeon, nurses and others in the room to smell the oil of bergamot or terpineol than to be constantly inhaling the odors of ether and chloroform.

At any time the anesthetist can give either chloroform or ether, or any combination of the two, by simply turning the single stop-cock, the change being made in less than a fraction of a second, all of the vapor passing through the third bottle, usually filled with hot water, and terpineol or a hot neutral oil. Unquestionably a smaller amount of anesthetic is used with this apparatus, or with some similar apparatus, than with any other method now known. It has been used constantly in some of our largest hospitals since 1905, with increasingly gratifying results in the following particulars:

1. A smaller amount of anesthetic is used. In a chloroform anesthesia, in which ether was contra-indicated on account of an ulcer in the stomach, I used 2 drams of chloroform for a twenty-five-minute operation. Two or three ounces of ether with one to two drams of chloroform per hour is the usual amount used.

2. The technic can be acquired with less danger to the patient than with any other anesthetizing method. In getting the patient entirely under, with this apparatus alone, excitement is usually absent, or so slight that it is unobjectionable.

3. In over 90 per cent. of the cases unpleasant after-effects are entirely absent.

4. A continual narcosis is always maintained, as we know exactly what per cent. the patient is getting at all times, and in addition the gradations are easily and readily made by moving the one lever according to the degree of narcosis demanded by the operation. An intermitting narcosis, which is wrong in principle, is thus avoided. It is especially indicated for nose and throat operations, and is the apparatus for mastoid operations. The anesthetist can maintain primary anesthesia, moving backward and forward between what is commonly known as the second and third degree of anesthesia, without once arousing the dangerous vomiting center. All of the vapor, being warmed, is more respirable, reducing the after-effects and increasing its safety as regards life. With this attenuated vapor, an infant three days old can be safely anesthetized and an alcoholic can be easily kept under, after reaching the surgical stage. All patients can be narcotized within five minutes, and with this warmed vapor, the kidneys, heart and lungs are never seriously affected.

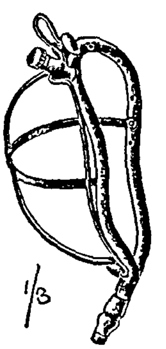

Fig. 2.

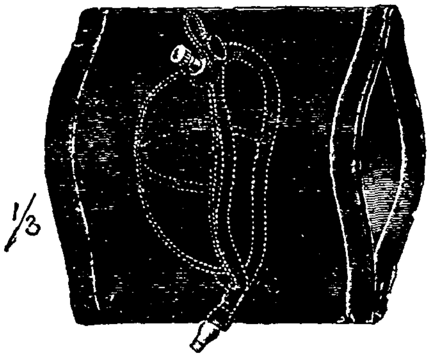

Fig. 3.

Fig. 2.—Illustration of mask one-third size.
Fig. 3.—Illustration of rubber covering for mask, which helps to prevent cooling and waste of the anesthetic.

In order to discover the value of passing this vapor through hot water, the following tests were made by Dr. Chas. Baskerville, professor of chemistry, College of the City of New York:

1. Pure oxygen was passed for seventeen minutes through 4 ounces of anesthetic ether, the resulting mixture passing through the hot-water bottle with the water at 60 C. The first 10 c.c. of distillate were collected. The ether used in this test had given a pronounced aldehyd reaction when allowed to stand over potassium hydroxid for six hours, but the distillate obtained in the above experiment gave only a slight response.

2. An experiment was made, using water at 40 C. and applying external heat to the water-container sufficient to insure vaporization of the ether. The ether distillate obtained under these conditions, gave a negative reaction for aldehyd. It will appear from these results that the aldehyd is removed when ether vapor is passed through water in the neighborhood of 40 C., and that the aldehyd content of the ether passed through is considerably diminished and its toxic value is especially lessened, when the water is kept at a temperature in the neighborhood of 60 C.

The vapor apparatus may be used in combination with a vacuum water pump, similar to the one used by dentists for removing blood and secretions from the mouth and throat in operations about those parts, in which it is necessary to remove the mask. The anesthetic vapor in this instance is administered through a metal tube attached to the delivery tube of the apparatus. I have improved the pump by the addition of an adjustable connection that can be attached to any hydrant or tap.

124 East Sixteenth Street.

EYE-STRAIN A CAUSE OF EXOPHTHALMIC GOITER

GEORGE M. GOULD, M.D.
AND
A. C. DURAND, M.D.
ITHACA, N. Y.

Exophthalmic goiter, it is said, is, or may be indicated by four symptoms, tachycardia, exophthalmo goiter, and tremor. Tachycardia is usually held to the early, leading, or primary symptom, the other three trailing off in relative unimportance. Indeed, any one or two, perhaps three, of the four may be absent, and yet the real morbific Proteus be present, concealed and yet pathogenic by means of the one or two remaining.

Pathology of a serious or rational standing has really nothing to offer as to the cause and nature of the disease. The oculists have kindly shoved the problem off into the far country labeled "ductless glands," and it has been quizzically suggested that the exophthalmic principality of the quadruple-crowned and loosely joined grand-duchies, owes all its independence to a wondrous little, and little wondrous, "muscle of Müller," situated at the orbital fissure. How it is possible for these tiny fibers by contraction to produce the distortion of a huge, or o any degree, of exophthalmos, with its attendant signs an symptoms, what may be the physiologic function of t muscle in the first place, and consequently what is morbid function, how the thyroid secretion can exec such a task—all these, and more, raise the corners the mouth of the genuine scientist. Indeed, the illog alities of the symptom-complex and of the group-na illustrate the tendency in all of us to clap an inappropriate name down on a lot of unknown facts, and "stand pat" in the comforting delusion that something has been done as regards etiology and therapeutics.

Now the forgotten *reductio ad absurdum* of this pathologic pathology lies in the fact that each day we all have patients presenting one, if not two, of these four "typical" symptoms, and we never dream of Dr. Basedow, or of Dr. Graves, or of Dr. Exophthalmic Goiter. Far more startling and undreamed of is the fact that we oculists who are also refractionists, have long been curing our patients who exhibit these symptoms, when they are presented singly, and doubtless also when in twos and threes. Nothing is more certain than that the eye-strain of ametropia often causes tachycardia, often causes tremor, often both combined. One of us has already reported a number of cases of tachycardia cured at once by the correction of ametropia, and we could add others. To these might be added cases of tremor. The coexistence of lateral spinal curvature must, and does, probably, add a causative factor, and certainly needs scientific study at the hands of serious-minded pathologists. The essential thing is to reach the precedent functional or physiologic cause of the late morphologic symptoms. In this respect all of our pathology is glaringly in fault and needs revolutionizing. When we find intense and long-continued eye-strain preceding the appearance of either of the three chief symptoms we at once get a glimpse into their possible origin, and especially if one after another is developed seriatim. This more particularly holds good if the exophthalmos is monocular.

What may be the mechanism whereby the symptoms are produced by eye-strain is another matter, and does not, at first, concern the clinician, or even the sensible pathologist, so much as the establishment of the fact. How tachycardia may be caused by eye-strain, and how tremor may result from eye-strain or scoliosis, is easily seen, but how exophthalmos is produced by eye-strain is not so readily understood. Less easily still may one explain the ocular origin, if such exists, of goiter.

Among a considerable number of cases that we have had which showed the causal relation of eye-strain and "Graves' disease" is the following:

July 15, 1907, Miss L. R., from Ohio, consulted us on the recommendation of Dr. I. She had been suffering from headache, lassitude, and intense pain in the back of the neck for a year, and the left eye began protruding about eight months previously, becoming more pronounced up to two months prior to her visit. No goiter existed. The pulse-rate was about 105, but variable. An oculist, some two months previously had ordered glasses, after three days of mydriasis, B.E. sph.+ 1.00!!! The static error of refraction, however, we demonstrated to be as follows:

R.+sph. 1.50,+cyl. 0.50, ax. 90°=20/30
L.+sph. 1.25,+cyl. 0.50, ax. 90°=20/30

For the ten or twelve hours during which the eyes were under the mydriatic the exophthalmos of the left eye disappeared almost completely, and this eye would not have seemed different from its fellow. When the cycloplegic wore off the next day the exophthalmos returned.

This temporary recession of an exophthalmic globe under mydriasis had occurred several times in our practice before, but in Miss R.'s case the sequel was different; for during the six months following the securing of the spectacles correcting her ametropia the exophthalmos slowly and finally completely disappeared.

Graefe's sign did not disappear under mydriasis, but in September, 1910, it was not present, and, so far as the exophthalmos is concerned, no difference was to be detected between the two eyes.

Of course the headache, neck pain, tachycardia, etc., passed away at once with the exact ametropic correction. At the last visit, also, all amblyopia had disappeared, the acuteness of vision being perfect. The ophthalmoscope revealed considerable ophthalmovascular choke, but the most decided symptoms of this disease were not present.

Nothing is needed to demonstrate the fact that in this case the cause of the exophthalmos and tachycardia was eye-strain. Whether goiter would, in time, have been added to the two other symptoms of hyperthyroidism, cannot now be asserted or denied.

The conclusion is suggested that, as multitudes of goitrous patients have no tachycardia or exophthalmos, the goiter symptom is somewhat independent or secondary. It appears more than suggested that a common, if not the chief, cause of so-called exophthalmic goiter is eye-strain. Probably the tachycardia is the first of the ocular reflexes instituted, followed by the exophthalmos, as, chiefly, a secondary vascular phenomenon. (The exophthalmos of choking, or strangulation, or cervical compression, is suggestive.) It is not beyond comprehension that heightened blood-pressure may induce goiter, although the neurotic origin seems more sensible. Lastly, it hardly needs mention that the only cure in such cases must be through prevention, stopping the long preexisting eye-strain by accurate correction of ametropia. Perhaps, rarely, may a cure be expected when decided exophthalmos (and especially of the *two* eyes) has been established.

For twenty years or more one of us (G. M. G.) has been urging the profession to make a differential diagnosis in cases of headache, migraine, neurasthenia, dyspepsia, etc., by cycloplegia. Not one has cared enough about the matter to carry out this simple test. Consequently, it would probably be of little use now to advise mydriasis as a method of testing whether the early symptoms of exophthalmic goiter are due to eye-strain. But why not?

ELEPHANTIASIS OF SCROTUM AND PENIS WITH OPERATION

RAYMOND RUSS, M.D.
SAN FRANCISCO

The following case history is presented because of the rarity of this condition on the Pacific coast. Tropical diseases about the Bay of San Francisco are rapidly increasing in number, and the practitioner must be on the constant lookout for them.

History.—A young man, aged 30, single, a cigar-maker by occupation, was referred to me for extensive swelling of the penis and scrotum. This patient had been in Mexico in 1900 for three months, and in 1902 for a period of six months. There was no other history of tropical exposure. He stated that the disease appeared insidiously and had never been accompanied by pain. There had never been periods of chill, high temperature or diaphoresis, but he said that at times there had been local heat in the scrotum, although unaccompanied by general fever.

Examination.—The scrotum was found to be very large, about the size of a small cocoanut. The penis presented an edematous collar, 4 cm. in width, just back of the corona glandis. On palpation the testes were found to be of normal size and freely movable within the scrotal sac. The size of the scrotum was due to an extensive involvement of its structure. The tissue was hard and brawny to the feel; it did not pit on pressure and was dark red to a light brown in color in places. The swelling was most noticeable directly under the penis, and extended to within 4 cm. of the perineum in the median raphe. The tissue resembled more than anything else the hard, brawny induration which so frequently occurs in the skin of the neck after extensive operation on its glands for malignant disease. There was no edema in any other portion of the body and the patient stated that there had never been any. One year ago the patient was operated on for adherent prepuce. This was only partially dissected away and the corona glandis was but partly clear at the time of my examination. At the frenum was a tumor mass of hard tissue closely resembling that of the scrotal involvement and about the size of a nickel, being possibly slightly thicker. This was made up of the adherent prepuce, and the mucous membrane of the glans penis was not involved. Back of the corona glandis there was a constriction of tissue of about 0.25 cm. in width, and above this point for at least 4 cm. the tissue was swollen and redundant, presenting the characteristics of the scrotal involvement. The femoral glands were not perceptibly enlarged. The patient's general health had always been good. The heart and lungs were normal. Tuberculin reaction negative.

This patient was referred to Dr. Herbert Gunn, who confirmed the clinical diagnosis of elephantiasis, and made several examinations for filaria, all of which were negative. The patient was placed on a hydragogue cathartic and the scrotal tumor was soon considerably reduced in size, but the skin induration was unaffected.

Operation.—September 9, 1910, at University of California Hospital the patient was operated on. I was fortunate in having present at the operation Dr. P. S. Rossiter, United States Navy, who has had a large experience (eighty-two cases) in the operative treatment of this disease in Samoa. The technic developed by Dr. Rossiter was carefully followed. With the patient in the lithotomy position, the lines of incision on the scrotum were outlined. They were made in perfectly sound tissue, meeting above on the under surface of the penis, then sweeping out in a slight curve to within 1 cm. of the perineum. The testes being well lifted, the tumor mass was grasped in the hand and rapidly cut away along the lines which had been marked. The testes were found to be normal. As the remaining lateral flaps were small, coaptation was obtained with some difficulty by means of tension sutures of chromic gut and the incision carefully united by a continuous horsehair suture. With a sound in the urethra the tumor mass near the frenum was removed by free incision and the prepuce dissected away from the corona glandis. Incision was then made transversely about and high up on the body of the penis, and the portion of involved skin between this point and the corona glandis removed. Sound skin was then brought down and united at the sulcus by means of four tension sutures of silkworm gut and a continuous suture of horsehair. The wounds healed kindly and the patient was discharged from the hospital on the eighteenth day.

240 Stockton Street.

A CASE OF CHRONIC APPENDICITIS SIMULATING NEOPLASM

W. H. BOESE, M.D.

Assistant Pathologist, Lebanon Hospital; Assistant Physician, University and Bellevue Clinic

NEW YORK

The following case is reported on account of the unusually large circumscribed development of inflammatory tissue, resembling a new growth. Although such a formation has been seen in chronic inflammation of the Fallopian tube, in the appendix it has not been reported to my knowledge.

History.—Miss D., aged 47, was admitted to the surgical service of Dr. Henry Roth at Lebanon Hospital June 2, 1907. About one year before admission to the hospital she had an attack of acute appendicitis. Soon after this attack subsided she noticed a mass in the right lower quadrant of her abdomen. This gradually increased in size. She lost 20 pounds in weight in one year. Examination revealed a tumor occupying the entire lower right quadrant of the abdomen, extending up to the level of the umbilicus and about one or two inches beyond the median line.

Operation.—This was performed by Dr. Henry Roth on June 3, 1907. On opening the peritoneal cavity a large mass presented itself with a shining, yellowish-brown surface and cystic to semisolid consistency. Its upper surface was attached to a broad band of omentum. There was an adhesion to the rectum. The tumor was intimately attached to the caput coli at the point corresponding to the base of the appendix. The mass was freed from the cecum and removed. In doing this there was an escape of very foul-smelling pus from the tumor through an opening at the point of its attachment to the cecum. The cecum did not show any evidence of involvement and, with the exception of denuded serosa and a small opening at the junction of the longitudinal bands, was normal in appearance. There was no evidence of any other growths or enlargements in other parts of the abdomen or body.

The patient died six days later, within a few hours after onset of symptoms of peritonitis, probably owing to failure of suture line in the cecum. Unfortunately a necropsy was not allowed.

Pathologic Report.—The tumor mass was oval, 19 cm. long, 11.5 cm. broad and 5 cm. thick. In the upper part, where it was attached to the cecum, and connecting with the lumen of the cecum by an opening about 0.5 cm. in diameter, was an oval abscess cavity about 6 cm. by 8 cm. by 4 cm. This cavity was filled with thick, yellowish pus, with a very offensive odor. Below the abscess cavity the tumor was one smooth, firm mass.

Sections were taken from four different locations. Dr. James Ewing of Cornell University was kind enough to go over the data and specimens with me. The following is his report of the more detailed findings:

"Sections from four portions of the tumor show that the growth is composed of fat tissue in various stages of edema and degeneration, a great many dilated veins, many large arteries and arterioles, many very cellular capillaries, considerable new connective tissue containing lymphocytes, lymph nodules, and plasma cells, and in certain areas diffuse infiltration with polynuclear leukocytes with some fibrin. There are also some outlying lobules of normal fat. None of the fat tissue shows any evidence of a tumor process, but rather of edema, mucoid degeneration, and invasion with an excessive number of small cellular blood vessels.

"In some areas about the numerous veins are broad sheaths of spindle cells with nuclei rich in chromatin. These show some of the features of a spindle-cell sarcoma, but are more satisfactorily explained as the result of chronic productive inflammation. Likewise, there are areas in which the small vessels and capillaries are so numerous as to suggest an angiosarcoma, but these appearances are probably the result of unusual cell multiplication in old granulation tissue. The typical structure of lipoma or liposarcoma is entirely wanting. The presence of diffuse suppurative inflammation in one large area, of much new inflammatory connective tissue, and of many lymphocytes, lymph nodules and plasma cells with granulation tissue, shows that the entire process is inflammatory and offers an explanation of the structures simulating a neoplasm.

"Therefore, the diagnosis may be given of chronic appendicitis and inflammation of the mesentery, with tumor like growth of inflammatory tissue."

527 West One Hundred and Forty-Third Street.

Dyspnea in Pleurisy.—Dyspnea is a very characteristic symptom of pleurisy. It is most urgent in those cases in which the exudation occurs most rapidly and it is astonishing the amount of fluid which a pleural cavity may contain without causing much distress of breathing, provided that it takes place gradually. There must, however, be some other explanation than the mere slowness of the exudation, as there are cases in which, even in spite of rapid effusion, the breathing remains unembarrassed. These cases give less anxiety, as the presence of urgent dyspnea is always a grave indication. —F. de H. Hall, in the *Practitioner*.

Therapeutics

HYPERTHYROIDISM (GRAVES' THYROID DISEASE)

When a child grows tall very rapidly, especially about the age of puberty, the thyroid is at least very active, or actually hypersecreting. The bone formation is rapid, and the epiphyses unite with the long bones at an earlier age than in children who grow more slowly. A young girl who has too much thyroid secretion is likely to have profuse or too frequent menstruation.

In not a few instances, during acute disease in which the heart becomes very rapid, the cause is not the disease, but the disturbance of the thyroid, or a mild thyroiditis, that is present.

In 1835, Graves, of Dublin, first described the disease with which his name is often connected. In 1840, Basedow, of Germany, again described the same affection. The most-used name of the disease, "exophthalmic goiter," is a misnomer and should be discontinued, as we may have this disease without exophthalmos, and exophthalmos may occur without other symptoms of this disease One of the two names at the head of this article is preferable, although proper names are objectionable for many reasons.

The greater the blood-supply and the greater the amount of simple hypertrophy, the nearer comes the thyroid gland to the condition [illegible] The greater the amount of colloid [illegible]ation of cysts, the nearer is the gland to what is known as ordinary goiter. The greater the amount of connective tissue and fibrous tissue development, the nearer comes the gland to undersecreting, sufficiently to cause myxedema.

In a beginning simple goiter, small doses of iodin may be of benefit, and iodin may be of benefit in the first stage of an exophthalmic goiter, the thyroid gland enlarging because it is short of iodin. In such conditions, the administration of small doses of iodin are of benefit, and a large thyroid, under such treatment, will often become smaller and the early symptoms of Graves' disease be inhibited. Such a gland, however, may be exceedingly susceptible to iodin, and a little iodin may precipitate all the Graves' symptoms. Or, the patient and the thyroid may stand small doses of iodin, while large doses would positively do harm, and are almost invariably inadvisable, as tending, sooner or later, to add the iodin cachexia to the thyroid disturbance. The iodin administered for this purpose is preferably in the form of an iodid, and perhaps best the sodium iodid. From 0.05 or 0.10 gm. (from 1 to 1½ grains) given from one to three times a day, is sufficient for saturating the thyroid with iodin and exciting its normal activity. Iodin has been used as an ointment, rubbed into the neck in the thyroid gland region. This, however, is generally inadvisable. The amount that will be absorbed is uncertain. Iodoform, in susceptible patients, placed on some absorbing surface, may cause iodin poisoning and symptoms of hyperthyroidism.

If during the administration of either iodin or thyroid symptoms of hypersecretion of the gland develop, the treatment is pernicious and should be immediately stopped. In fact, in any enlargement of the thyroid the administration of thyroid substance should be tried with great care lest the gland be stimulated to the condition of Graves' disease.

There is no justification for giving large doses of thyroid extract to a patient with a goiter with the expectation of diminishing it in size. It may be thus reduced in size, but the symptoms caused by such thyroid feeding should prohibit its use to that extent. The injection of iodin into goiters is not justifiable, and the attempt to diminish the size of the goiter with *x*-ray treatment is of questionable value. While the gland may be thus reduced in size, the skin is caused to become adherent to the underlying tissues, and any future necessary operation becomes much more serious than when the *x*-rays have not been used.

When any treatment is undertaken to diminish the size of the thyroid, its frequent variations in size without any treatment must be taken into consideration before deciding that such treatment was beneficial.

With these preliminary considerations we are better prepared to study "exophthalmic goiter." Its causes are any of the stimulants of the thyroid gland which have been named as stimulants in the previous article. It is suggested that in some instances exophthalmic goiter has followed some previous general infection, the gland having been first stimulated by such infection and then has continued its activity. Such a cause is probably rare, as sclerosis and subsecretion of the gland are much more likely to follow such irritation. The disease occurs four times as frequently in women as in men and most frequently between the ages of 20 and 40.

SYMPTOMATOLOGY

This disease or condition is well studied by dividing it into four periods: first, the prethyroid period; second, that of incipient symptoms; third, the period when the symptoms are all actively present, the stage of exacerbation; and fourth, when the symptoms of the disease tend to decrease, or the stage of defervescence. While deaths do occur from the disease itself during its exacerbation, it is probably rare. Death, however, often occurs during hyperthyroidism from some intercurrent affection or necessary operation, or from an operation that unfortunately must be done on account of serious symptoms, but has been deferred too long.

1. Rapid development of hyperthyroidism is doubtful, although it has long been stated that it may develop rapidly after some mental shock. Almost invariably careful questioning will show that there were plenty of signs present of hypersecretion of the thyroid. Highly neurotic patients, especially women with uterine irritations, as caused by inflammation or displacements are liable to the development of this disease. Recurrences of tremblings, palpitations, sleeplessness, vasomotor disturbances, and inexcusable loss of weight are signs that this gland could readily become so stimulated as to produce the picture of hyperthyroidism. Any of these conditions may be but short-lived, but if frequently repeated, they show a tendency to hyperactivity of this gland.

2. The actual symptoms of a developing Graves' disease are, primarily, an increased rapidity of the heart, some enlargement of the thyroid, and nervous irritability. These symptoms the patients often themselves note, perhaps not the enlargement of the thyroid, but questioning will often disclose the fact that they do not like collars or laces tight around the throat.

If in doubt as to whether these symptoms (especially if the thyroid apparently is not enlarged) are due to hypersecretion of the gland and are symptoms of beginning Graves' disease, the administration of a thyroid tablet (3 grains) once a day, will in five days at least, clear up the diagnosis. If the patient has increased thyroid secretion, every symptom will be greatly intensified. If these symptoms are not intensified, the patient is not beginning an exophthalmic goiter.

3. The three prominent symptoms of an established Graves' disease are exophthalmos, enlarged thyroid, and palpitation of the heart. The most constant of these three symptoms is palpitation, and the next most constant is enlargement of the thyroid. The exophthalmos is frequently absent, and often is present in but slight degree. Exophthalmos may be present with an enlarged thyroid without palpitation. This combination, however, is infrequent, and the gland is not really hypersecreting. Rarely but one eye is affected. The forward projection of the eye-ball is probably due to dilated blood-vessels at the back of the orbit, as the exophthalmos disappears after death. The thyroid may be enlarged as a whole, but often only half of it is enlarged, and it varies in size from time to time, causing varying sensations of pressure. Part of the gland may increase its colloid material and even show cystic degeneration while the rest of the gland may continue to hypersecrete.

Palpitation is almost always present more or less persistently, lasting sometimes for weeks, and under the same conditions at the same rate. In other words, a patient who has a palpitation of 130 in the office during examination of the heart may be found for weeks, under the same conditions, with the same frequency of heart rate. No other disease or condition will allow a patient to walk around and attend to his or her business, eat, drink, sleep, and even be merry, with a heart-beat of from 120 to 140, and not recognize that he or she is suffering from palpitation. Any other cause for such a rapid heart will always cause dyspnea, more or less cardiac distress and actual disability. Sometimes the pulse is irregular, rarely intermittent. Often it is a pretty good pulse, even at the rapid rate. The heart is generally hypertrophied, especially the right ventricle, and later in the disease it may become dilated. There may be insufficiency of the valves on account of cardiac enlargement, but there is no valvular lesion. The future danger to the heart is that of a myocarditis. The arterial pressure is often low, but may be normal, and it is occasionally higher than normal. One of the serious dangers in the radical cure, *i. e.*, by operation, of this disease is that the operation is not done until myocardial weakness has developed. The carotid arteries pulsate to the point of throbbing and the thyroid arteries are dilated and also throb. This pulsation in the neck is exceedingly annoying to some of these patients. Aneurysms of the thyroid arteries often occur, giving all sorts of roarings and murmurs in and around the region of the gland.

The fourth most frequent symptom of Graves' disease is tremor. It is almost constantly present, may be of the hands alone, often of the tongue, and it may even be difficult for the patient to hold the head still, especially when being examined.

Other symptoms that may be present are a cough, due to the pressure of the thyroid and due to large blood-vessels in the throat, especially in the lingual tonsil region. These pressures and dilatations cause tickling. Diarrheas may occur, and sometimes nausea and vomiting; often severe headaches and insomnia are symptoms. There are vasomotor ataxias, such as hot flashes and then a feeling of coldness, and one may feel the patient's hands or face at one time cold, or hot, and in four or five minutes they feel the opposite.

Another important symptom of the disease is loss of weight, which is almost constant and has often progressed considerably before the patient comes to the physician; but there is always a limit to this loss of weight, as it does not seem to be continually progressive.

Early in the history of the disease the patient often sweats readily; sometimes has dripping perspirations. This, however, is by no means constant, and is probably due to the vasomotor disturbance. Leg and muscle weaknesses, and sometimes edema of the feet and ankles occur. This is entirely due to a weakened circulation. There may be polyuria, and sometimes an albuminuria, which perhaps represents passive congestion of the kidneys from weakened heart, and occasionally there is glycosuria.

The eye symptoms are characteristic, and the different signs are known by the names of the men who first called attention to them. Names are confusing, and it is unnecessary to quote them. The characteristic signs of the exophthalmic eye are (1) the inability of the upper eyelid to follow the eye-ball on looking down; (2) the unusual amount of sclera disclosed above the cornea caused by retraction of the upper lid when the patient is looking forward; (3) the difficulty or actual inability of the patient to hold the eye in a position of convergence. There may also be involuntary winking and tremor of the eye-ball. There may be, from the pressure, an obstruction of the mouths of the tear-ducts, and the tears may flow down the cheek, although the eyes may become dry.

The skin is generally thin, soft, and moist, and as the blood-vessels of the surface are more or less dilated, perspiration is generally easily caused by the least nervous excitement. There is more or less diminished electrical resistance of the skin, which is perhaps due to the overfilled blood-vessels on the one hand, and to the increased central nervous excitability on the other. Pigmentations of the skin are found on different parts of the body and not infrequently on the eyelids. Sometimes there is falling of the hair, or it may become prematurely gray. There may be browning of the skin, not dissimilar to what is seen in pernicious anemia or in Addison's disease, or there may be vitiligo. There may be all kinds of eye, ear, and head symptoms.

4. The duration of the disease may be from two to ten years or more. If the disease is to end in death, the complications which bring this about are most frequently myocarditis, diabetes, or a progressive muscular debility and neurasthenia. A pernicious anemia may also be a final outcome. Severe nervous complications may develop, but are rare, such as melancholia, mania, or chorea. If active thyroid disturbance has continued for more than five years, the chances of complete recovery are small, as serious complications have generally occurred. Those patients who recover generally do so in from two to three years by a general amelioration of the symptoms, with a tendency, as previously stated, some years later, to a sub-secretion of the thyroid and partial myxedema.

The majority of patients with this disease, properly treated, will certainly recover, and the better understanding of the treatment and the curative value of early operation as now understood, will probably produce 75 per cent. of recoveries. If left alone, probably not more than a small percentage of patients die of the intensity of the disease itself, but most patients die from complications.

PROGNOSIS

It is impossible to estimate the probable duration of the disease in a given instance. If there is a family tendency to neuroses, or if the patient has shown symptoms long previously of neurotic temperament, the recovery will be slow. If the onset of the disease was rather rapid the recovery will probably be more rapid. The older the individual with exophthalmic goiter, generally, the sooner may recovery be expected. Younger patients who recover from the disease are likely to have recurrences. Most patients may be greatly improved even without operation; quite a percentage can be cured without operation; a certain percentage can never be cured without operation. The constantly better prognosis from operation when done early in the disease should cause physicians not to allow a prolonged tachycardia from Graves' thyroid disease to persist, as a heart muscle may become permanently damaged, and then the prognosis of an operation is serious. Also, great loss of weight should not be allowed before an operation is advised. The danger of permanent invalidism and diabetes should always be remembered and a patient should not be allowed to suffer with the disease for years without operative interference having been early suggested and urged.

TREATMENT

First, when the disease is not positively in evidence, but suspected, a small dose of thyroid, as above suggested, should be given daily for a few days or a week, not more than 0.20 gm. (3 grains) of the official thyroid powder once a day. If the symptoms are aggravated, the thyroid is hypersecreting and the patient is in danger of Graves' disease. The treatment at this time, after the diagnosis has been made, is not dissimilar (except that bed rest is not urged) from the treatment of the actual disease.

Meat, coffee, tea, and alcohol should be entirely cut out of the diet. Sexual excitement should not be allowed. Any uterine disturbance should be investigated and corrected, if possible. Some simple iron preparation should be administered, and the elixir of the glycerophosphates of lime and soda is indicated, especially as it has been shown that when there is exophthalmic goiter there is increased elimination of calcium in the urine, also, the lime salts seem to act as a sedative to the thyroid gland. If a patient is well-nourished and in good physical and blood condition the bromids may be given for a time, but should not be long continued, and generally are contra-indicated by the debility and weakness. Most patients, especially when meat is stopped, should receive a small dose of iron each day. On this treatment the majority of these patients will recover, although they may have relapses.

If the thyroid is distinctly enlarged and a few of the symptoms of Graves' disease are present, small doses of iodid may stimulate the gland to more normal activity so that it will not secrete abnormally. This may be tried when active symptoms of Graves' disease are not present. If they are present the iodid will generally make the symptoms worse, as does thyroid feeding.

If the disease is actually present and with all the classic symptoms, the most important symptom is the rapid heart action. Anything that will reduce a pulse of 130, 140 and even more to 100 or 110 is of benefit. Such a patient must be put to bed, and must stay there for the period necessary to quiet the heart. The diet should be that above outlined. Such laxatives as necessary should be given, and daily massage should be done. The glycerophosphates of lime and soda should be tried, and if these do not quiet the heart or the symptoms of hypersecretion, perhaps the best treatment is the hydrobromid of quinin, given in 0.30 gram (5 grain) doses, three times a day. It may at first cause a little cinchonism, but soon this is not noted, and it seems sometimes to have specific action on the thyroid, and much better action than the sulphate of quinin. Rarely in such severe cases should bromids be given, as they will add to the debility that is present and coming. Atropin in any form is generally of little value, and sometimes seems to excite the nervous system, if in doses sufficient to show its action. Suprarenal substance or extract is of no value. Thymus gland substance has often seemed to cause some improvement, and at other times has absolutely failed. Opium in any form (morphin, codein, or other alkaloid) will always diminish the thyroid secretion, but the future is bad, and such administration is rarely justifiable.

Digitalis is of no value in reducing the frequency of the heart beat when it is stimulated by thyroid secretion. The patient may be poisoned with digitalis and the heart not slowed at all. Strophanthus may be given if the heart is weak, but it will not slow it. Strychnin is generally contra-indicated on account of increasing the nervous irritability. The heart must be quieted with calcium preparations and mental and physical rest, which can best be obtained in a hospital or sanatorium.

Ergot (and it must be a good ergot, a sealed bottle of a pure fluid extract) in a dose of half a teaspoonful given in water, three times a day after meals, may be of benefit in quieting the heart and contracting the peripheral blood-vessels, and should be tried.

Any active electrical treatments of the thyroid, as faradization, galvanization, cataphoresis, or any local counterirritant action, or the rubbing in of ointments are almost invariably of no avail, and often do more harm than good. In fact, the less the gland is manipulated the better.

The application of the *x*-ray to a gland has been declared by some skilled operators to be of value. It has been tried frequently without success, however, and it is certainly inadvisable if a future operation is contemplated. It injures the skin, makes the skin adherent to the gland and tissues below, and may interfere with perfect healing. In other words, it does not present a good surgical field.

When the Roentgen ray treatment is successful, it has been noted that the gland diminishes in size, and therefore its secretion is probably diminished and the tachycardia is lessened.

The milk from thyroidectomized goats has been administered with good results: also various serum preparations prepared from animals that have been thyroidectomized have at times seemed to furnish an antidote to the hypersecretion of the thyroid, but such treatments, though logical, have not been attended with more than occasional success. An antithyroidin has been presented, which is prepared from the serum of thyroidectomized sheep, the dose of which is 4 grams, (1 drachm) three times a day. Also a thyroidectin has been put on the market, prepared from the same source, put up in capsules, the dose of which is one or two, three times a day. Any of these treatments should be continued for from four to eight weeks, and then repeated at intervals of two or three months.

Beebe and Rogers, of New York, have used successfully an antithyroid serum prepared by them from the serum of Belgian hares after they have injected the animals with serum obtained from exophthalmic goiter thyroids. The serum so prepared has seemed to act as an antitoxin. If the patient develops an immunity or does not any longer improve with the serum from this animal, they use a serum prepared from some other animal. Injections are given every forty-eight hours. The shorter time the disease has been in existence, the greater the success of the treatment. Lately, Dr. S. P. Beebe, of New York, has stated his belief that extracts of human thyroids, carefully prepared and administered hypodermatically, are by far the best for the human subject. By careful analysis he has come to the conclusion that any portion of the prepared protein that contains about 0.0034 of iodin represents 1 gram of the active protein. He prepares tablets of different strengths representing 1, 2, and 5 per cent. He understands that a 1 per cent. tablet means that 1 per cent. of the dried weight of the tablet is made up of the purified thyroid protein. For hypodermic use he makes various strengths standardized on the iodin basis, put up in sealed glass tubes.

From the degenerations that take place in the thyroid glands of patients with Graves' disease, and from the disturbance that this disease causes in other parts of the body, and also taking into consideration the question of whether the gland disturbance is the primary cause of Graves' disease, the number of successes from such serum injections must be limited. Also, the difficulty of obtaining a sufficient amount of this serum, which must be prepared from the removed exophthalmic goiter glands, must allow but a small portion of patients with Graves' disease to be so treated.

Consequently, when any patient with exophthalmic goiter does not quickly improve with the medicinal treatment above suggested or with the antithyroid treatments that may be readily applied, resort should be had to surgery, and partial thyroidectomy is indicated. Such an operation is indicated if three or four months of medical treatment has not caused marked amelioration of the symptoms; if the exophthalmos is likely to injure the sight; if there is great loss of weight and strength; if the tachycardia persists; and if there is any serious pressure on the esophagus, trachea, or nerves. Such operations are successful in removing the symptoms of the disease. Contra-indications to operation are, as above stated, a weak heart muscle as shown by an irregular and wavering tension pulse; edemas that would show lack of cardiac compensation would also contra-indicate operation. Frequent attacks of diarrhea should postpone such an operation.

The substitute operation of ligating one or more of the enlarged thyroid vessels may ameliorate some of the symptoms, but such ligations are often only temporary in their benefit. The danger of pressing too much thyroid substance into the circulation during ligation is almost as great as during the operation for partial excision.

The *prognosis* is much better in early operation in Graves' disease than later, on account of the liability of the whole gland to become disturbed in its function, and the probability that other ductless glands are consequently disturbed in their functions, perhaps permanently. It seems to be a fact that different parts of the thyroid may be functioning differently although the complementary secretion may be nearly normal. Consequently, if it is possible to determine the portion of the gland that is especially diseased, it should be that portion which is removed. Sometimes the healthy portion of the gland has been removed and the diseased portion left, and death has occurred on this account. The removal of one lobe of the gland, the most diseased portion, with perhaps the isthmus is generally a sufficient operation. Of course as many parathyroid glands as possible should be left. It is rare, and then perhaps only when there is carcinomatous degeneration, that the whole thyroid should be removed. If it is necessary to remove the whole gland, and consequently perhaps most of the parathyroid glands, parathyroid substance or extract, or some calcium salt at least, should be administered for some time to prevent convulsive symptoms from such extirpation. Later, thyroid feeding would prevent myxedema.

Dr. C. H. Mayo, Rochester, Minn. (*Ohio State Med. Jour.*, October, 1907) believes that ether is the best anesthetic to use, and half an hour before the ether is begun gives a hypodermatic injection of 1/6 of a grain of morphin, and 1/120 of a grain of atropin. The morphin prevents the necessity of much ether and the atropin prevents the profuse mucus secretion. He places the patient in the reverse Trendelenburg posture which tends by gravity to relieve the upper part of the body of blood. He leaves the posterior capsule of the gland undamaged and thus preserves the parathyroids. Of course the recurrent laryngeal nerve is looked for and protected. He washes the wounded area with Harrington's solution (alcohol 640 parts, water 300 parts, hydrochloric acid 60 parts, bichlorid of mercury 8 parts). This prevents lymphatic absorption. The patients after the operation are given large saline enemas. If they do not retain these, they are given saline solution subcutaneously. This treatment he repeats several times during the first thirty-six hours If the patients sweat profusely he gives atropin. If they are very restless he gives morphin. Most patient are not confined to bed more than three days.

Dr. T. P. Dunhill (*Brit. Med. Jour.*, May 22, 1909 believes that local anesthesia governs the whole questio as to the safety or danger of the operation from exopl thalmic goiter. He does not believe that general anesth sia can be recommended as safe, while local anesthe may be recommended as perfectly safe, unless patient is moribund.

Drs. Max Ballin and J. W. Vaughan, of Detroit (*Jour. Michigan Med. Society*, April, 1910) come to following conclusions as to the final results of thy ectomy in Graves' disease:

First: Early operation before secondary heart eye changes have occurred practically assures a c the victim of exophthalmic goiter. They wo operate during the height of an exacerbation of ease, but after absolute bed rest in which the symptoms have quieted down, what might be t interval operation.

Second: In no case in which the symptoms have be present for a period of over five years and in which p manent heart changes and eye changes have occurr can a positive recovery be promised, although the c dition may be much improved. These are the danger cases for operation, and each must be studied treated according to the symptoms.

The Medical Profession in Norway.—Recent statisti that there are now 1,161 registered physicians in Norw eighty-eight residing in foreign lands, sixty-four being United States. The average in all Norway is one p to 2,007 inhabitants, but in Christiania there is on cian to 850 inhabitants. The age of 66.3 per cent. is 30 and 50: only 5.3 per cent. are between 25 and 30. 3.1 per cent. over 70. Editorial comment on these f the *Norsk Magazin for Laegevidenskaben* calls attention small number of physicians surviving past 50 and th proportion who are ready to practice before the age

RECENT STUDIES ON TYPHUS FEVER

It will be recalled that Nicolle of Tunis, in Africa, recently succeeded in transmitting typhus fever to the macacus monkey, and that Anderson and Goldberger, working independently with the disease as it is found in Mexico City, were able to infect monkeys with blood taken from typhus patients. These results were further confirmed by the investigations of Ricketts and Wilder. Recently Gaviño and Girard[1] report the transmission of typhus to monkeys of an inferior species, namely, the *Ateles vellerosus,* indigenous to Mexico, by subcutaneous injections of blood from typhus patients. The animals, after an incubation period of eleven to fourteen days, succumb to prostration and a high fever. An exanthematic eruption, such as occurs almost constantly in man, is absent, but the thermal elevation and other symptoms are regarded as sufficiently characteristic to permit the diagnosis of typhus. Immunity is conferred by a single injection so that the monkeys after their recovery from the disease are fected by subsequent inoculations. Other animals, as the white rat, white mouse, rabbit, dog, pig and all proved insusceptible to typhus fever.

Mexican authors report also one experiment in ey seem to have obtained a protective vaccina- the inoculation of a monkey (*Ateles*) with l blood from a patient in the twelfth day of a attack of typhus fever. Four c.c. of the defi- d blood were sealed in a glass tube and heated for minutes at 55 C. The control animal received amount of unheated blood, and after an incu- riod of fourteen days passed through a charac- d severe attack of typhus fever. The monkey ved the heated blood showed a slight rise of e during the three days after the injection, suggested, to toxins liberated by the destruc- microorganisms in the heating. An immunity sisting of the injection of fresh typhus blood phus patient was given and no febrile reaction ppreciable malaise resulted, although the control sickened fifteen days after his injection of the same blood and died five days later. Unfortunately the experiment as yet stands alone, the scarcity of monkeys interrupting the investigation. We hope that further experiments may be made, as they promise results of practical value in the working out of a successful vaccination against typhus fever.

Gaviño and Girard also studied the blood of typhus patients. No cultivable germ was discovered, but the forms recently described by Ricketts and Wilder were found in the plasma. These structures in smears stained with Giemsa solution appear in three forms: (1) as bipolar bacilliform bodies, two microns long and one-half micron wide, with rounded ends, the poles staining a violet purple and the interpolar substance not at all, (2) similar bacilliform bodies in which a pale violet-staining mass is seen in the central part between the poles; (3) bodies measuring one and one-half microns in length formed of two spherical granules separated by a space in length twice the diameter of the granules, one granule colored a reddish purple with Giemsa, the other blue.[2]

Gaviño and Girard are of the opinion that the bodies represent products of nuclear disintegration and karyolysis rather than microbes. They base their conclusion on the study of smears from the spleen of one of their diseased monkeys in which they claim to find granules which in some instances show clearly the origin from the nuclei of the leukocytes and in others simulate closely the bodies seen in the blood plasma.

Since 1883, when Mott described diplococci in the blood of typhus patients, numerous microorganisms have been put forward as the specific cause of typhus. Among the more important of these are, a strepto-bacillus obtained by Hlava in 1888 on various culture media, a diplococcus described by Dubief and Bruehl, and a piroplasma seen in the blood by Gottschlich in Alexandria. All, with the exception of the last, were cultivated, but as these observations have not been confirmed, the consensus of scientific opinion seems to be that the problem of the causal agent of typhus still remains unsolved. The bodies described by Ricketts and Wilder cannot be cultivated. Their bipolar structure reminds one of the plague bacillus and this is of interest in view of the similarities between typhus fever and plague: both diseases are acute, self-limited, blood infections; both are associated with subcutaneous hemorrhages; both are apparently insect-borne. It has been shown that plague is carried from host to host by the flea and recent investigations point strongly to the louse as the transmitter of typhus fever. These and other theoretical reasons entitle the bodies in question to very careful consideration, and the results of further investigations are awaited with interest.

Gaviño and Girard. Pub d Inst Bact Nacional, Mexico, 1910

[2] Prieto describes other phases of the research in the Cronica Medica Mexicana, 1910, xiii, 314.

DIABETES

The important and practical group of communications on the subject of diabetes by Lusk, McLeod, Woodyatt, Pratt and Wallace, which appears in this issue, is worthy of special attention. The papers represent the principal lines along which the work on diabetes is being advanced. The surveys of the literature will be found to be critical, and the commentary to be based on new data which represent definite progress worthy of attention.

Lusk calls attention to the fact that in cases of the severest forms of diabetes mellitus or phlorhizin diabetes in which the glycogen deposits in the body have become exhausted, the sugar in the urine comes solely from protein, provided no starch or sugar is ingested. Under these circumstances the total urinary sugar comes to bear to the total urinary nitrogen a constant ratio, viz., 3.65 grams sugar to 1 gram nitrogen. This means that about 60 per cent. by weight, *i. e.*, the possible maximum, of the protein metabolized has been converted into sugar, all of which is then excreted. In another place Lusk has called this a "fatal ratio," as it indicates a complete loss of tolerance for sugar and a hopeless prognosis. Such a method of making a forecast is significant of what one day will be the rule in medicine. In attaching significance to such a ratio it is, of course, understood that the ratio must be found steadily on successive days, for in cases of no great severity a transient accidental ratio of about 3.65 to 1 may be encountered during a period in which a heavy discharge of sugar from liver glycogen is taking place into the blood. "The intensity of diabetes," says Lusk, "should not be determined by the percentage of sugar in the urine, but by the relationship between the ingo of sugar (or starch) plus the possible maximum of sugar production from protein, as compared with the total output of sugar," a relationship which when expressed in the form of an equation, as done by Falta, gives his "coefficient of excretion." By means of Falta's coefficient a total absence of sugar tolerance is designated as 100. Milder deficiencies of tolerance may be expressed by any whole number or fraction between 0 and 100, thus doing for diabetes what the sphygmomanometer does for arterial pressure, or the erythrocyte count and hemoglobin estimate do for the gauging of an anemia. This employment of figures for expressing the severity of a diabetes will result in a sharper definition or the gradual discarding of such terms as "mild," "moderately severe," "severe," etc., which are now so much employed and with different meanings in different localities. And yet there are those who still, in referring to diabetes, talk about "a 2 per cent. urine," and in other conditions, notably in pregnancy and Bright's disease, draw conclusions from the percentage of urea, with no regard for the total quantities excreted. There are others, too, who do indeed estimate the total quantity of sugar or of urea, especially the latter, and even of nitrogen and other substances, and then draw conclusions innocent of all knowledge concerning the total amount of protein and non-nitrogenous food which the individual has eaten and by which the amounts of the substances found in the urine are so markedly influenced. By feeding experiments in which he has employed certain simple components of the protein molecule, Lusk is in a position to state that the ability of protein to pass over into sugar is inherent in certain of the component amino-acids and is not due to preformed sugar in the protein molecule.

Woodyatt, working with certain simple sugars, some of which may be regarded as the components of the glucose molecule, brings experimental evidence to show that in the course of the utilization of sugar in the body a cleavage of glucose into two molecules of triose is an important event. He also shows a suggestive parallelism between certain oxidations of sugars which can be performed in the laboratory and those oxidations of sugar in the body which have to do with the checking of acidosis—the chemistry of the latter process receiving therein its first specific consideration.

In keeping with a modern tendency to reexamine some of the teachings concerning diabetes which have been regarded as fixed, McLeod's detailed study of the mechanism of the form of diabetes produced by irritation of certain parts of the nervous system is able and highly suggestive. In Claude Bernard's puncture of the floor of the fourth ventricle McLeod sees a stimulation at the center of a reflex arc, the efferent limb of which runs in the splanchnics and whose effect is to lessen the power of the liver cell to hold its glycogen, *i. e.*, to lessen the inhibition which normally keeps glycogenolysis (or the conversion of glycogen into sugar by the action of glycogenase) within its normal limits. He believes that the asphyxia glycosurias and certain of those caused by organ extracts are ultimately of the same mechanism as the form caused by splanchnic stimulation. Epinephrin glycosuria he is inclined to regard as part and parcel of the well-known action of epinephrin on the sympathetic autonomic nervous system. So in the case of thyroid glycosuria and other experimental forms McLeod registers a protest against a too general tendency to interpret the effect in terms of pancreas inhibition. Even in diabetes mellitus he suggests that a deranged glycogenic function of the liver may contribute to the picture in some degree. In this connection it is interesting to note that Wallace in dogs made diabetic by total pancreas extirpation—a condition which soon clears the liver of glycogen—sees no effect from the use of atropin, whereas Rudisch and some others find by its use an amelioration of glycosuria in diabetes mellitus. Fluctuations in glycosuria caused by such drugs as atropin and opium are greatest in cases in which the liver still holds glycogen.

Pratt's work on the sugar tolerance of dogs before and after ligation of the pancreatic ducts leads him to believe that ligation of the ducts, if thoroughly done, will result in some loss of tolerance for sugar, if not in real diabetes, contrary to a general belief. After such ligations he fails in some instances to find in the atrophic pancreas rest any Langerhans tissue, but only connective tissue and remnants of acinus cells and duct epithelium. He concludes, from this and other considerations, that the production of an antidiabetic principle is not confined to island tissue. The problem is technically beset with many difficulties. Wallace reiterates what so many have found to be true and what is nevertheless so doggedly disregarded by hundreds of physicians, that save in certain special situations or emergencies there is no drug that is effectively employed in the treatment of diabetes mellitus.

THE SOCIAL AND LEGAL VALUE OF VITAL STATISTICS

Physicians, individually and as a class, have long realized the value of trustworthy vital statistics as a basis of knowledge regarding diseases. Owing to their efforts in urging the passage of vital registration laws, the general public, members of legislatures and even physicians themselves, have largely lost sight of the non-medical value of vital statistics. The passage of such laws has come to be regarded as a favor to physicians and as a matter in which the general public has little, if any, concern. Yet the recording of births and marriages is of no advantage to physicians as such; they are interested in vital statistics only as these contribute to sociologic knowledge. The registration of deaths is useful to the medical profession only in affording information regarding the frequency and mortality of disease. Hence the interest of the medical profession in vital statistics legislation is, at most, entirely impersonal and altruistic.

The subject, however, should be of the greatest interest to all citizens, because it is important that every individual should be able, if necessary, to produce legal evidence of his birth and parentage. It is important that records should be made of the time, place, manner and cause of death of every human being. Registration of vital facts is of the greatest value in determining questions involving parentage, legitimacy, inheritance, property rights, marriage and divorce—in fact, in most of the social or business relations of life. The value of proper registration of these essential facts has long been recognized by all civilized nations except our own. The utter neglect of vital registration by many of our states is a constant source of astonishment to visitors from other countries. In this connection, an article by Deacon,[1] the statistician of the Kansas State Board of Health, is worthy of comment. Our neglect of such fundamental and truly vital matters can be accounted for only by the comparative newness of our social organization. Each state, as it becomes older, and as social relations become more complicated, will find it necessary to provide some effective means for registering essential facts regarding its citizens. It is particularly strange that, in the southern states, where the possibility of racial admixture is greatest, and where even a suspicion of tainted ancestry carries with it the gravest social consequences, there has been little effort to make or to preserve legal records of birth. The reason for this neglect must surely be that the legal and social importance of vital statistics registration has never been properly brought to the attention of the public leaders in the South, for certainly when it is appreciated, these states will not delay the adoption and enforcement of appropriate laws on this subject. It is not conducive to national pride to know that such countries as New South Wales, Tasmania, New Zealand, Ceylon, Jamaica, Finland, Roumania, Bulgaria, Japan and Chili are far ahead of the United States in the proper registration and preservation of records on vital matters. Still less gratifying to our self-satisfaction is Mr. Deacon's statement that the United States in this particular must be classed with Africa and Borneo.

THE PREVENTION OF INFANT MORTALITY

The deliberations of the American Association for the Study and Prevention of Infant Mortality, the first annual session of which was recently held, culminated in a series of five resolutions, which, though different in subject, are all in harmony with the aims of the association.

The first of these resolutions deals with the establishment of a national department of health, and shows a broad conception of the essentials of the movement for the prevention of infant mortality. Concerning this particular resolution, a report of the meeting[1] says that Prof. Irving Fisher described the sinister commercial influences that are hypocritically hampering the establishment of a national health department under the pretense of safeguarding "medical freedom," and showed how such a branch of the federal government might become a supremely efficient instrument in the promotion of all those matters of public hygiene and legal enactment on which the reduction of infant mortality depends. The association went on record as "endorsing the movement for a national department of health, in the belief that the establishment of such a department will lead to great reduction in infant mortality, *not only through* improved regulation of interstate commerce in milk, infant foods, and medicines; *but also through* wider dissemination of information on the causes of infant mortality and their prevention."

---

[1] Deacon, W. J. B.: Vital Statistics in Relation to Public Welfare, Jour. Kansas Med. Soc., November, 1910; abstr. in this issue of THE JOURNAL, p. 2172.

[1] Bruère, R. W.: Saving the Babies, Survey, Nov. 26, 1910, p. 317. A report of the meeting is now running in THE JOURNAL, in the Department of Society Proceedings.

The report of the committee on birth registration, by Dr. Cressy L. Wilbur of the Bureau of the Census, inspired a resolution endorsing the model law of the American Medical Association for the registration of births and deaths. This precipitated, incidentally, an interesting discussion, led by Dr. W. H. Welch, on the midwife question, which resulted in the appointment of a committee to formulate a definite policy on this subject.

The third resolution urged on the Secretary of Agriculture the establishment of official standards for milk "branded as certified, inspected or pasteurized" and the enforcement of such standards in interstate commerce.

The remaining resolutions related to instruction of pupils and teachers in elementary hygiene, sanitation and biology in the public and normal schools and in colleges, and the need of safeguarding mothers from industrial and economic pressure and of instructing them in the principles of healthy parenthood and infant hygiene.

This is an ambitious program, but it touches the vital points in the prevention of infant mortality.

Current Comment

READY-MADE MIXTURES

There is little doubt that the tendency in some quarters to underestimate the value of drugs in the treatment of disease is due to the unscientific way in which drugs have been used rather than to the lack of efficacy of the drugs themselves. No reliable conclusions can be deduced regarding the use of drugs unless the administrators of such drugs know the exact amounts that have been used; in other words, accuracy of dosage is essential to scientific therapeutics. In the Pharmacology Department of this issue, one of the reasons for unscientific prescribing is made clear. There are on the market tablets containing bismuth, opium and phenol in varying (alleged) proportions. Whether these tablets were originally made by the various manufacturing pharmaceutical houses in response to a demand by physicians or, as is more likely, were put out by an enterprising firm to catch the physician's fancy makes little difference. The point is, such tablets are on the market, made by a number of large and reputable concerns, and the supposition is that the tablets are prescribed where definite amounts of bismuth, opium and phenol are indicated. Yet careful investigation extending over two years, made in the Association laboratory, proves beyond question that so far as the phenol-content of these tablets is concerned, the dosage is absolutely unreliable. Whether this unreliability is due to the technical difficulties of making such tablets, to the lack of care, or even to actual dishonesty on the part of the manufacturers, may be open to discussion, but it is indisputable that such tablets cannot be scientifically prescribed. Not only should physicians cease prescribing such products, but self-respecting pharmaceutical houses should cease manufacturing them or else should acknowledge openly that the formula on the label does not represent the actual composition of the product.

ENDOWMENTS FOR MEDICAL EDUCATION

A few years ago President Eliot aptly stated that "the way to get endowment for medicine was to improve medical education." So the best policy for medical colleges to pursue is not to wait, Micawber-like, for something to turn up, but to find out what they need and then to go after it. In some instances this may require, before starting the campaign for ample financial support, an energetic house-cleaning and the making of mergers or other changes so that the college will deserve endowment. That this is a wise policy has been repeatedly shown. The faculty of Drake University College of Medicine voted to close the school unless money enough was forthcoming to conduct the college in accordance with modern standards. As a result $150,000 was raised in a few weeks' time. In Colorado there were two medical colleges, one of which, being in a small city, lacked ample clinical facilities and the other, owing to insufficient finances, lacked ample laboratory equipment. It was decided to merge the two schools so that the strong points of one could be made to supplement those of the other. This was done with the result that one strong college remained in Colorado with a unified medical profession back of it. A later instance is at Western Reserve University, Cleveland. Last June the trustees determined to raise a million dollars to endow the medical department, and then set about to get it. It is now reported that nearly $700,000 has been raised. There are numerous localities where such successes may be duplicated if the right steps are taken. The local college or colleges, however, must take the initiative and make all the improvements possible before seeking help elsewhere. The college should first show itself capable of the proper use of funds entrusted to it and then the funds will be forthcoming.

NEW VIEWS ON WOUND-HEALING

While the more ambitious dreams of the surgeons of the pre-Listerian era in regard to wound-healing have been fulfilled, according to Carrel's article in this issue, we have no right to believe that the treatment of wounds has reached its ultimate perfection. We content ourselves as yet with securing a degree of asepsis, and leave to Nature the healing of the wound and the care of cicatrization. Carrel believes that we may be able to go farther than this and to activate the processes of repair, so that wounds which, under our best present methods, heal in a few days, may heal in a few hours; that the development of methods for the stimulation of the growth of epithelial cells, for the inhibition or activation of connective-tissue proliferation and the artificial production of osteogenesis would greatly improve the therapeutics of ulcerations of the skin, and of lesions of the peripheral nerves, the bones and many other tissues. With a view to the development of this new principle of surgery, Carrel has undertaken some animal experimental studies to ascertain the laws of the redintegration of tissues. It is a custom of florists to use chemicals for the activation or "forcing" of the growth and maturation of flowers, aside from the use of the ordinary fertilizers, heat, etc. Analogous processes may be invoked in the growth and repair of tissues. Carrel's first article concerns regeneration and cicatrization of surface wounds, and he deduces from his studies certain preliminary principles which are of interest, and which indicate results of the highest importance in wound-healing.

TYPHOID FEVER AND BUSINESS

Sometimes the connection between excessive typhoid fever and the commercial welfare of a town stands out so clearly that the most reluctant observer must grant its existence. This seems to be the case in Rutland, Vermont, where typhoid epidemics in 1909 and 1910 have been attributed to the water-supply. Financial retribution has followed at once. The managers of conventions scheduled to meet in Rutland have changed their intentions and the conventions have met in other places; a wealthy New Yorker who had purchased land and planned a costly residence in Rutland writes to the local paper that he cannot carry out his plan unless protection of the water-supply is assured; there is now talk of damage suits against the city by typhoid victims. Altogether the financial aspect of a polluted water-supply has become very prominent. The Rutland *News* is driven to remark that "there is no question that Rutland has suffered grievously in a business way during the past two years as a result of these annual visitations of typhoid. It is simply good common business sense that the source of the epidemic be eliminated. Commercial prudence, if nothing more, requires it." The experience of Rutland may serve to remind city officials, who deny the existence of danger from a sewage-polluted water-supply on the ground that other sources of typhoid fever exist in the community, that water-borne typhoid may be slow in appearing, but that it is likely when it does occur to bring more discredit and financial loss to a city than typhoid from any other source.

Medical News

ARKANSAS

Library for Sanatorium.—The people of Little Rock have made a liberal response to the appeal for the establishment of a library at the Arkansas Tuberculosis Sanatorium, Booneville. More than 100 volumes were donated on the first day of the appeal, and it is intended that a permanent library shall be established. It is also suggested that magazine subscriptions be donated.

Personal.—Dr. Harry C. Stinson, Little Rock, superintendent of the State Hospital for Nervous Diseases, has notified the Board of Trustees of State Charitable Institutions that he would not accept reelection for another term and asked to be released from duty at the expiration of his present term of office.——Dr. Sterling B. Gammill, Branch, fell from his buggy, November 29, fracturing three ribs.——Dr. L. O. Hunter, Branch, has moved to Chismville.

ILLINOIS

Physicians' Club Election.—At the meeting of the Physicians' Club of Monmouth, December 2, Dr. Chauncey Sherrick was elected president, and Dr. Joseph R. Ebersole, secretary.

Personal.—Dr. and Mrs. William A. Haskell, Alton, have gone to Bermuda for the winter.——Dr. James H. Walker, Effingham, having passed the required examination, has been commissioned captain and assistant surgeon and assigned to the Fourth Infantry.

Verdict Against Surgeon.—In the third trial of the case of Mrs. Carrie Smith against Dr. Ernest B. Mammen, Bloomington, in which damages were claimed on account of the alleged leaving of a sponge in the abdominal cavity after a surgical operation, a jury in the circuit court is said to have brought in a verdict for the plaintiff, assessing damages of $1,500.

State Board Prosecutions.—S. Hirschfeld, a graduate of the National Medical University, charged with practicing medicine without a license, is said to have been found guilty and fined $200.——In the case of Susannah Dyba, charged with practicing without a license, and said to be an old offender, the defendant is said to have been fined $200 and costs.——In the case of J. A. Nowlin, an osteopath charged with the administration of medicine and also with the practice of surgery, the case was dismissed on account of lack of evidence. The license of osteopaths in Illinois licenses to treat human ailments without using medicine and drugs or the performance of surgical operation.——In the suit brought by the State Board of Health against J. B. Albright, Kewanee, a licensed osteopath, for a similar offense, the defendant is said to have offered to pay a fine of $100 and engage no more in the practice as a physician, but does not wish judgment in court brought against him. The board declined to accept this proposition.——W. J. Bourque, an optician of Chicago, charged with practicing medicine without a license, is said to have been convicted by a jury in the municipal court of Chicago, December 6, and fined $100 and costs.——Madam M. L. La-Mounte, a fortune teller of Chicago, charged with practicing medicine without a license, was found guilty and fined $100 and costs, and paid the fine.——Harrouton Shekerjian, Chicago, charged with practicing medicine without a license, is said to have been found guilty and fined $100 and costs. The fine was paid.——In the suit brought by the board against H. F. Fairfax, Chicago, for practicing medicine without a license, the defendant is said to have been found guilty and fined $100 and costs.

Chicago

Personal.—Dr. William A. Mann, who has been seriously ill with pneumonia, is reported to be convalescent.——Dr. E. L. Cornell, intern in Cook County Hospital, has recovered from an attack of diphtheria.——Dr. William E. Morgan, who was operated on for appendicitis recently, has returned home recovered.

Urge Retention of County Physician.—The new president of the Cook County Board has received letters from many prominent physicians of the city recommending that Dr. Haim I. Davis be retained as county physician on account of the record which he has made in that office, and expressing the hope that political reasons will not cause Dr. Davis' removal.

INDIANA

Personal.—Dr. Louis Severin, Bluffton, health officer of Wells County, has resigned to take effect Jan. 1, 1911.——Dr. Charles W. Shill, Lafayette, has been appointed physician for the Tippecanoe County jail and infirmary.

Superintendent Wanted.—The Board of Trustees of the Indiana State Tuberculosis Hospital, Rockville, is now receiving applications for the position of superintendent of the institution, who will be employed as soon as appropriation is made for maintenance. All applications and recommendations should be addressed to Dr. Henry Moore, president of the board of trustees, Room 25, State House, Indianapolis.

Built Within Appropriation.—The tuberculosis hospital commission, which had in charge the construction of the State Hospital, Rockville, at its meeting, November 30, reported that the hospital was constructed and finished ready for occupancy, with about $100 of the appropriation of $130,000 left to revert to the state treasury. The committee also reported more than $1,000 turned into the state treasury from earnings from the hospital farm during the construction of the building.

Club Interested in Pure Food.—The Board of Directors of the Commercial Club of Indianapolis, has signed a petition favoring the enactment of a federal law regulating the manufacture and sale of food containers and food put up in food containers, compelling the marking of the containers so as to show the net capacity and net quantity contained and providing penalty for violation of these provisions. The club is also endeavoring to interest capitalists of the city in building sanitary tenement houses for the poorer classes of foreigners.

State Health Board Recommendations.—The State Board of Health, at its meeting, November 26, decided to make the following recommendations to the General Assembly: medical inspection of all public schools; approval of the board to plans and specifications of all public buildings before contracts are let; additional legislation to further restrict the pollution of streams, giving the board greater power in the prevention of such pollution; greater power to the board for the prevention of the pollution of sources of water-supply of the state, and greater power to the board in governing the construction of sewers.

IOWA

Ill in Hospital.—Dr. Emma J. Neal, Cedar Rapids, is reported to be ill with typhoid fever at Mercy Hospital, Cedar Rapids, ——Dr. Irving C. Wood, Logan, is ill in the Clarkson Hospital, Omaha.

Small-Pox in Border Town.—The alleged failure of the town officers of Bradyville, Page County, to enforce the state quarantine law in face of an epidemic of small-pox, has caused action to be brought by both the Missouri and Iowa state boards of health as Bradyville is just across the Iowa line from Missouri. The mayor states that there have been fifty cases of small-pox in the town, and that at present there are twenty-two cases in eighteen families.

Southeastern Iowa Physicians Meet.—The thirty-fifth annual meeting of the Southeastern Medical Society was held in Fort Madison, November 17, and the following officers were elected: president, Dr. Clyde A. Boice, Washington; vice-presidents, Drs. Frank C. Roberts, Fort Madison, and Smith A. Spilman, Ottumwa; secretary-treasurer, Dr. Edward F. La Force, Burlington, and censors, Drs. John F. Herrick, Ottumwa; Henry A. Leipziger, Burlington, and Frank R. Mehler, New London. It was decided to hold the next meeting in Washington.

MARYLAND

Personal.—Dr. Earle H. Sneavely, assistant physician at the Springfield State Hospital for the Insane, has been appointed third assistant physician at the Essex County Hospital, Overbrook, N. J.——Dr. Thomas B. McDonald, Cumberland, has been appointed physician of Allegany County.

Typhoid Fever in Troop A.—Dr. Alexius W. McGlannan, Baltimore, chief surgeon, Maryland National Guard, has reported on the cause of the epidemic of typhoid fever in Troop A of the organized militia of Maryland, following the encampment at Gettysburg last summer, which affected the health of eleven and caused one death. He thinks the extension of the disease was probably due to the custom in the troop of using a loving-cup and to an infected milk-supply. He recommends in future, preliminary examination of men, prohibition of fresh milk in camps, and that men submit to antityphoid vaccination.

Baltimore

Conference on Hygiene.—A conference on hygiene, with an exhibit, is to be held in Baltimore about February 1, under the auspices of the Medical and Chirurgical Faculty of Maryland. Dr. Marshall L. Price, secretary of the State Board of Health, will be in charge of the exhibit.

Personal.—Mr. J. Bosley Thomas has been made chemist and bacteriologist of the water department.——Dr. Frederick C. Blanck has been appointed chemist of the city chemical laboratory.——Dr. H. E. Kelsey has been elected vice-president of the North Carolina Society of Maryland.

Local Society Election.—At the annual meeting of the Baltimore City Medical Society, December 6, the following officers were elected: president, Dr. Arthur M. Shipley; vice-president, Dr. Ridgeley B. Warfield; secretary, Dr. William E. Magruder; treasurer, Dr. William S. Gardner; censor, Dr. Charles W. Larned, and delegates to the Medical and Chirurgical Faculty of Maryland, Drs. Richard H. Follis, Archibald C. Harrison, Standish McCleary, William A. Fisher and James M. H. Rowland.

MASSACHUSETTS

Unlicensed Practitioner Fined.—Jeremiah Scopa, East Boston, is said to have been found guilty, November 15, of practicing medicine without a license and to have been fined $100.

Many Medical Alumni.—According to the new directory of Harvard University, recently issued, Harvard now has 3,337 graduates in medicine. This does not include the graduates in dentistry.

Society Election.—At the annual banquet and election of officers of the Somerville Medical Society, held December 1, Dr. Frank L. Morse was elected president; Dr. Robert F. Gilson, vice-president, and Dr. Frederick N. Stephens, secretary-treasurer.

Physician Pardoned.—Dr. Ovid M. Paulhaus, Haverhill, sentenced to state's prison five years ago for having performed a criminal operation which resulted in the death of a Haverhill woman, was released November 25, after having served five years of his six and one-half years' imprisonment.

NEBRASKA

Gubernatorial Appointments.—Governor-elect Aldrich has made the following appointments: Lincoln Hospital for the Insane—superintendent, Dr. John T. Hay, Lincoln (third appointment); physician, Dr. Benjamin F. Williams, Tamora; pathologist, Dr. Lawrence B. Pilsbury, Lincoln; Hastings Asylum—superintendent, Dr. William B. Kern, Grand Island; Norfolk Asylum—superintendent, Dr. Andrew Johnson, Omaha; and penitentiary—physician, Dr. L. R. Jones, Amherst.

Society Elections.—Saline County Medical Society held its annual meeting in Crete, December 8, and elected the following officers: president, Dr. Howard W. Quirk, Crete; vice-president, Dr. Henry Hein, Wilber; secretary-treasurer, Dr. Porter F. Dodson, Wilber; and delegates to the state medical society, Drs. Francis J. Stejskal, Crete, and William S. Warder, Friend.——Lancaster County Medical Society, at its annual meeting in Lincoln, December 3, elected the following officers: Dr. John M. Mayhew, president; Dr. Warwick M. Cowgill, vice-president; Dr. Roy B. Adams, secretary-treasurer; Dr. Eduard W. Rowe, censor; and Drs. J. Stanley Welch and Henry J. Lenhoff, delegates to the state medical association, all of Lincoln. Dr. Francis F. Tucker, formerly of Lincoln, for many years a medical missionary in China, addressed the meeting on "Native Practice in China."

NEW YORK

Mayor Vetoes Action of Council.—Mayor Fuhrman of Buffalo has vetoed the recommendations passed by both houses of the city council, which were to the effect that the joint committee, which is investigating the necessity of building a general city hospital with a pavilion for communicable diseases, should visit other cities where such hospitals exist.

The Day Camp.—The Buffalo Day Camp for Tuberculosis has now been open for three seasons, 108 days in 1908; 141 in 1909; and 157 days in 1910. During this season there was an average daily attendance of 43, and 15,000 meals were served, exclusive of the morning and afternoon lunches. Germany, Poland and Italy were the nations most largely represented at the camp.

Low Death Rate.—The monthly bulletin of the State Department of Health for October, reports 10,942 deaths, equivalent to an annual mortality of 14.5 per 1,000. In October, 1909, the rate was 15.5, and in September, 1910, 15.4. About 21 per cent. of the deaths occurred during the first year of life. There was an increase in the number of deaths from cancer and a decrease in epidemic diseases, pulmonary tuberculosis, diseases of the nervous system, diseases of the circulatory system, pneumonia, and bronchitis.

Personal.—Dr. George A. Newton, Freeport, has succeeded Dr. Edwin Carman as health commissioner.——Dr. William B. May, milk inspector of the Department of Health of Buffalo, has been appointed chief of the State Department of Health, vice Dr. William A. Howe, made deputy commissioner of health of Buffalo.——Dr. Eugene A. Smith has returned to Buffalo and resumed practice.——Dr. Thomas H. McKee, Buffalo, has returned from abroad.——Dr. Alva Le R. Chapin, Niagara Falls, was seriously injured in a collision recently when his automobile was struck by an Erie freight train and demolished.

New York City

Gift to German Hospital and Dispensary.—The trustees of this institution have formally accepted the gift of Mrs. Anna Woerishoffer of $100,000 to be used to found a children's ward to be known as the Dr. Abraham Jacobi Ward.

Epidemic in East New York.—The outbreak of diphtheria and scarlet fever in East New York which was first noted about two weeks ago has assumed epidemic proportions. There are at present about 200 children under surveillance of the inspectors. The scarlet fever is of a mild type.

New York Subscribes Half a Million.—On the eve of the annual meeting of the Red Cross Society it is announced that New York city has completed its apportioned sum, based on ten cents per capita population, for the $2,000,000 endowment fund of the society. New York was the first city to complete its quota.

Another Open Air Classroom.—The architects for the city have filed plans for an open air room and diet kitchen on the roof of the two-story public baths and gymnasium on the north side of Carmine street which will cost $6,000. The room will accommodate as an open air classroom fifty children inclined to tuberculosis.

Dinner to Dr. Weir.—A dinner was given at the University Club, in New York, December 10, in recognition of the half-century of service to the profession by Dr. Robert F. Weir. About a hundred were present, including a large proportion of men who had served as house surgeons under Dr. Weir. Among the speakers were Drs. Maurice H. Richardson, Boston; William L. Rodman, Philadelphia, and William S. Halsted, Baltimore. The proceedings included the presentation of a silver cup to Dr. Weir.

PENNSYLVANIA

State Tuberculosis Exhibit to Go to Wales.—The Pennsylvania Society for the Prevention of Tuberculosis received a request from Wales, December 3, for the loan of its educational exhibit, to be shown in a campaign against tuberculosis now being organized in that country. The request comes from Thomas Jones, secretary of the Welsh National Memorial to King Edward the Seventh, accompanied by the statement that of all the exhibits at the International Congress of Tuberculosis, held in Washington, 1908, that of the Pennsylvania Society was considered the best.

Health Conference.—The Western Pennsylvania Public Health Conference, organized at the instance, and under the auspices of the Central Council of the Associated Charities, was held in Pittsburg, November 29 and 30 and December 1. The opening session was addressed by Dr. Sidney E. Goldstein on "Hospitals and Health Agencies of the Pittsburg District and Their Specific Problems and Needs." The next session was devoted to the general subject of "Dispensaries, Their Places and Function, Methods of Cooperation Among Them, Their Opportunities and Responsibilities for Affecting the Home Conditions and Home Care of Patients;" the opening address being delivered by Dr. Richard C. Cabot, Boston. Remarks were also made by representatives of eighteen dispensaries of Pittsburg, presenting features of their work and suggestions in line with the theme of the meeting. At the first evening session, the general subject was "Restoration and Prevention, How the Curative and Preventive Work of Hospitals and Other Health Agencies may be Promoted and Developed by Developing Social Service and the Human Interest Point of View, Side by Side with Scientific Professional Skill and Material Equipment." Dr. Richard C. Cabot, Boston, delivered an address at this session on "Social Service in Hospitals and Dispensaries," and Dr. Samuel G. Dixon, Commissioner of the Pennsylvania Department of Health, delivered an address illustrated by stereopticon views on "How Pennsylvania Fights Tuberculosis by Improving the Homes, Occupations and Habits of the Tubercular." Nursing was the general topic of the morning session on Wednesday with the theme "How Should Nurses be Enlisted, Selected, Trained and Directed for Competent Service in Hospitals, Dispensaries and Private Families." "What are the Essentials for Visiting Nursing Service to the Poor in Their Homes?" The principal address was by Miss Adelaide Nutting, Johns Hopkins University. Dr. Henry M. Hurd, superintendent of Johns Hopkins Hospital, opened the discussion on hospital cooperation by an address on "To What Extent is it Desirable and Practicable to Develop Means and Habits of Cooperation Among the Hospitals in the Purchase of Supplies, Relations with Employees, Admission of Charity Cases, Publication of Needs Encountered and Work Accomplished in the Holding of Conferences as to Common Problems and in Any Other Appropriate Ways," followed by five-minute remarks from representatives of thirty-five hospitals. Efficiency and finance was the general topic for the evening session, the theme being "By What Standard or Test Should the Work of Hospitals, Dispensaries and Nursing Agencies be Measured?" and "To What Extent and Under What Supervision Should Financial Support be Provided Through Public Funds?" with an address by William H. Allen. The discussion was taken up under the general heads of instruction, subsidies and support. At the morning session of the third day, "Children's Health Agencies" were considered, and in the afternoon the general subject was "Investigation and After-Care of Charity Cases." Dr. Charles P. Emerson, Superintendent of Clifton Springs Sanitarium, delivered an address on "Should Applicants for Free Treatment or Charity Rates be Investigated Before or Upon Admission, and Followed up with Friendly Service After Dismissal?" The discussion was taken up under the general heads of self-help, investigation, after-care, practicability and cost. The afternoon session was devoted to a young men's rally, when the subject "The Young Men's Health Problems, Including Sex Hygiene," was discussed. At the closing session of the conference "Community Education" was considered under the general theme "How May Sickness be Prevented and Good Health Promoted by Improving the Homes and Habits of the People Through Popular Education." The principal address, on "Educating the City," was delivered by Dr. William A. Evans, health commissioner of Chicago.

Philadelphia

Parrish Portrait for College.—At a meeting of the College of Physicians, held December 7, a portrait of Dr. Joseph Parrish was presented by Dr. James Tyson on behalf of the donor. Mrs. Susan Parrish Wharton. Dr. Parrish was born Sept. 2, 1779, was elected a member of the college in 1810 and died Mar. 11, 1840.

Consumptives' Open-Air School.—Preparations are being made for the establishment of an open-air school for the instruction of boys and girls suffering with incipient tuberculosis, which will be under the joint care of the Board of Education and the Department of Public Health and Charities. The school will accommodate more than 100 pupils and classes will be heard out-of-doors during the whole school term.

Personal.—Dr. Louis P. Posey has been appointed a member of the State Board of Medical Examiners, vice Dr. Caleb S. Middleton, resigned.——Dr. Edward Martin has been made Barton professor of surgery in the University of Pennsylvania vice Dr. J. William White, resigned. Dr. Martin and Dr. Charles H. Frazier have been nominated to the board of trustees by the medical committee of the board.——Dr. John G. Clark gave a dinner, December 6, in honor of Dr. Franklin H. Martin, Chicago. Plans were arranged for a clinical meeting of the Physicians of North America in this city in November, 1911, one similar to that held recently in Chicago.——Dr. Matthew H. Cryer, professor of oral surgery in the Dental School of the University of Pennsylvania, has been made editor of the *Imperial Stereoscopic Anatomy of the Head and Neck*, a magazine published by D. D. J. Cunningham and Dr. David Waterson, of the University of Edinburgh, Scotland. ——The directors of the poor of Chester County have chosen Dr. Ralph C. Kell, Philadelphia, as superintendent of the Chester County Hospital for the Insane.

GENERAL NEWS

Academy Mid-Year Meeting.—The fourth annual mid-year meeting of the American Academy of Medicine was held in Buffalo, December 1, under the presidency of Dr. Charles S. Sheldon, Madison, Wis. The conference dealt with the sociologic influences of hospitals and dispensaries.

Personal.—Dr. Wilfred T. Grenfell of Labrador, has been visiting in Charleston, S. C., on his way to the north from Florida.——Dr. Hamilton P. Jones, New Orleans, food commissioner of Louisiana, has been elected second vice-president of the Association of State and National Food and Dairy Departments.——Dr. Robinett B. Hayes, Fayetteville, N. C., has been elected grand regent of the Kappa Psi Fraternity.

Journals Consolidate.—The *Southern Medical Journal* has consolidated with the *Gulf States Journal of Medicine and Surgery*. The editorial office will be Suite 905 Van Antwerp Building, Mobile. The editor-in-chief is Dr. Seale Harris, and the managing editor, Dr. Henry A. Moody, both of Mobile. The associate editors are Drs. John A. Witherspoon, William D. Haggard, Worcester A. Bryan, William Litterer and James M. King, all of Nashville, Tenn. The journal will be conducted on the same high-class lines as before.

The Cartwright Prize.—The Cartwright Prize, valued at $500, biennially awarded by the Association of the Alumni of the College of Physicians and Surgeons, New York City, will be next awarded at the commencement exercises in 1911. Essays to be held worthy of the prize must contain original investigations made by the writer; must be on medical, surgical, or kindred subjects; must be typewritten and in English, and marked with a device or motto, and accompanied by a sealed envelope similarly marked, containing the name and address of the author. The payment of the prize money to the successful essayist will be made on his filing with the treasurer of the association a printed copy of the essay. Essays in competition must be sent to Dr Henry E Hale, secretary of the Association, 770 West End Avenue, New York City, on or before April 1, 1911

FOREIGN NEWS

Other Deaths in the Profession Abroad—General H Laub, surgeon general of the Danish army, died November 12, aged 72, from cancer of the rectum Since his appointment in 1902 as chief of the medical department, it has made great progress under his initiative——The cable also brings word of the death of Professor Henri Huchard of Paris, an authority on diseases of the heart, aged 66 He founded about 1887 the *Revue Clinique et Thérapeutique* and later the *Journal des Praticiens*, and some of his works on the circulatory system and on neuropathology are text books in regular use

Death of Mosso.—The leading physiologist of Italy and a pioneer in the physiology of life at high altitudes, Prof A Mosso, professor of physiology at the university of Turin, died November 24, aged 64 years He founded the *Archives Italiennes de Biologie* in 1882 to present in French the results of the research of Italian workers in this line, much of his own work was published also in Virchow's *Archiv*, especially his monographs on the circulation, respiration, ptomains and functions of the bladder Among his books are "Fear," Fatigue," 'Temperature of the Brain" and "Man in the Higher Alps" He was long a senator, and for his advocacy of athletics was called "the apostle of physical exercise" He was also instrumental in founding the Monte Olen international institute for nature study above the snow-line

Cholera—No cases of cholera have been reported to the sanitary authorities since last June from Spain, Portugal and some of the South American countries, nearly every other country, however, has had cases either in ships in the harbor or on land, but except in the endemic foci no serious epidemic has developed although conditions were threatening in Italy for a time Naples had 329 cases, with 131 deaths between September 25 and November 8, but no new cases have been reported from Naples since November 16 and vessels are resuming their schedules Fourteen provinces of Italy are now infected with cholera, the total number of cases outside of Naples in the six weeks ending November 16, amounting to 536 with 234 deaths, but only forty four cases were reported throughout the kingdom during the following week and none in Naples or Rome No cases have been reported at any time north of Rome and only a few cases have occurred there In Russia the number of officially reported cases by November 19 had reached 213,941 with 99,882 deaths In the countries immediately adjoining Russia to the west the occasional imported contagion is speedily stamped out and no serious trouble has resulted, although Hungary had recorded 288 cases with 139 deaths by October 15

CANADA

Hospital Burns—The Toronto Free Hospital for Consumptives, Weston, was totally destroyed by fire, December 1, with a loss of $100 000 The ninety two patients were all removed without casualty

War on Opium—A bill was introduced into parliament, November 30 by Mackenzie King, minister of labor, making it a punishable offense to use opium except for medicinal purposes The present laws prohibit the importation, sale, or manufacture of opium

Cholera on Royal George—Dr J George Adami, Montreal, announces that although there was a real case of cholera diagnosed on the steamer *Royal George* there is no reason for anxiety, as the cholera microbe is practically harmless in cold weather The thirty seven steerage passengers have been released from detention and sent to their respective destinations

Two Canadian Periodicals Unite—The merger of the *Montreal Medical Journal* into the *Canadian Medical Journal*, the official organ of the Canadian Medical Association, which was announced in these columns October 1, is accomplished With the December issue, the *Montreal Medical Journal* ceased to exist as a separate publication The first issue under the new arrangement will appear in January under the editorial management of Dr Andrew MacPhail, Montreal

Society Elections—The Winnipeg (Man) Clinical Society has elected the following officers president, Dr James G Munroe, vice president, Dr Julius E Lehmann, secretary Dr. Oscar C Dorman, treasurer, Dr. Raymond S Brown, and executive committee, Drs. John H. R Bond, W. H Reilly and Fred A Young——The following territorial members of the Ontario Medical Council have been elected· Drs George R. Cruickshank, Windsor, Albert B Welford, Woodstock, Alexander D. Stewart, Fort William, and Thomas W G Young, Peterboro

Hospital Notes.—The Saskatchewan government has decided to locate the new provincial hospital for the insane at Battleford, and has voted $100,000 for the purpose The land has been secured and building operations will begin in the spring.——Guelph, Ont, is to have a tuberculosis hospital——A new children's hospital is to be erected in Hamilton——A tuberculosis sanatorium is to be installed at Windsor on the old Her homestead——Mrs Jordan of Boston, Mass, has informed the New Brunswick government of her intention to present the property at River Glade, consisting of 700 acres with a large three story house and several other buildings, valued at $30,000, to the government to be used as a tuberculosis hospital

Personal—Dr Murray MacLaren, St John, N B, has returned from abroad——Dr Hugh L Dickey, Van Anda, B C, has removed to Honolulu, H T——Dr Everind A Kirkpatrick, Halifax, is convalescent after severe illness——Dr John C. Mitchell has been transferred from Brockville Hospital for the Insane to the Coburg institution——Dr Edmund E King, Toronto, has been reelected a member of the Ontario Medical Council for East Toronto——Dr David J Dunn has been appointed school health officer of Edmonton, Alta——Drs Pierre A Valois and Joseph A Beaudoin have been appointed civic health officers of Lachine, P Q——Dr Bruce L Riordan, chief surgeon of the Grand Trunk Railway, Toronto, is seriously ill with typhoid fever——Dr Richard J Monahan, Glace Bay, N S, has been appointed senior surgeon of the Canadian Naval Service——Dr Bruce Hill, Winnipeg, who sued the Winnipeg Electric Railway Company for damages for injuries received while a passenger, has been awarded $2 000 and costs

LONDON LETTER

(From Our Regular Correspondent)

London, Dec 3, 1910

Quackery and Nostrums in Great Britain

There are signs that the government will abandon the indifference which has rendered this country an unrestricted happy hunting ground for quacks and nostrum exploiters Recently the government sent forms to the 1,600 health officers of the United Kingdom inviting their opinion on "whether the practice of medicine and surgery by unqualified persons is assuming larger proportions and as to the effect produced by it on the public health" The result is embodied in a recent report On the whole the answers do not point to a large increase in unqualified practice, though such might have been expected from the profusion of advertisements of quack remedies and "specialists" The increase seems to be most marked in large centers of population, but curiously, quackery appears to flourish less in London than in provincial towns The most extensive form of unqualified practice is prescribing by pharmacists, which is practically universal They constantly prescribe for minor ailments or what are believed to be minor The poor are particularly fond of resorting to them because it costs less than going to a doctor In some districts a doctor seldom sees a child of the working class which has not been purged or otherwise treated for several days by a pharmacist Diseases of the skin, the eye, and venereal diseases are much treated by pharmacists, who often also undertake dentistry, and are the chief agents for the sale of nostrums But they sell the latter only when demanded, they prescribe their own preparations if possible, for the profit on their sale is much greater Next to pharmacists come "herbalists"—persons with no pharmaceutical qualification whatever, who sell herbs and other drugs as far as the law allows The only restriction they suffer under, compared to pharmacists, is that they cannot sell poisons They are numerous and rapidly increasing in the large manufacturing towns of Lancashire and Yorkshire As they have no legal status they are more reckless than pharmacists They treat all sorts of diseases, and even visit patients—a thing seldom done by pharmacists "Bone setters" are extensively in vogue in some parts, especially in mining districts, and some of the large friendly societies even accept their certificates as equivalent to that of a physician Of the more fantastic sorts of quackery 'Christian Science" is increasing in several northern towns.

In Yorkshire and Durham the practice prevails of diagnosing and treating ailments by persons in a hypnotic state One great evil from unqualified practice is the spread of infectious disease from failure to diagnose it Cases are quoted of small pox diphtheria, scarlet fever and other diseases being spread in this way In cancer valuable time is lost because the disease is not recognized in its early stage and is then treated by useless drugs

A large section of the report is devoted to nostrums These are purchased extensively by all classes, rich as well as poor The facility with which they can be obtained is strongly condemned They have enormously increased the amount of self drugging, and in the case of incipient disease, such as phthisis they often give rise to delay until the condition is incurable The suggestion is made that the composition of all advertised remedies should be stated, that their analysis should be determined by government analysis at the vendors' expense that the sale of headache powders and similar drugs should be prohibited, and that the sale of infants' food should be regulated For the other forms of unqualified practice no remedies are suggested, and it is difficult to see how they could be In this country the liberty of the individual is held so high that it would be impossible to prevent a person who is ill from taking any advice from any one he wishes The quack labors under only one disadvantage compared with the physician If a patient dies under his treatment he is liable to be indicted for manslaughter But this scarcely ever happens, as medical advice is generally sought before the end If it does happen, he is generally acquitted, as he is held to have done his best and the jury come to the conclusion that medical advice would not have saved the patient

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov 25, 1910

Protection of Infancy Against Tuberculosis

The eighth general assembly of the organization called La Préservation de l'enfance contre la tuberculose, founded by the lamented professor Grancher, was recently held under the presidency of Dr Roux, director of the Pasteur Institute The purpose of the organization is to remove children of tuberculous families from danger of infection, and to place them in the country among the families of healthy peasants living under good hygienic conditions Only absolutely healthy children, aged from 3 to 13, are accepted The organization has at present a budget of $31,000 (155,000 francs), and has twelve offshoots in the principal cities of France It has 425 protégés distributed in the provinces When the guardianship of the society ceases, the children often remain as agricultural laborers in the localities where they have been placed

Election of Two Correspondents of the Academy of Medicine

In its session of November 22, the Académie de médecine elected, as national correspondents, Dr Lebayle, former intern of the Paris hospitals, dean of the León medical school at Nicaragua and Dr Oui, professor of obstetrics and of the hygiene of early infancy at the Lille medical school

Cholera and a New International Sanitary Conference

In response to a question from a member of the Chamber of Deputies, the minister of the interior has officially made a statement to the effect that the question of a new international sanitary conference has been under consideration for some time Before undertaking a revision of the agreements obtained at the last sanitary conference it is indispensable to make sure that Turkey, which by its geographical situation and the movements of Mussulman pilgrimages, is particularly exposed to the importation of epidemics, should consent to conform to the international sanitary regulations Accordingly the minister of foreign affairs has used his influence to induce Turkey to enter into the sanitary union It seems now that Turkey will be disposed to accede and to call a new sanitary conference soon at Constantinople If these intentions are not realized the initiative no doubt will be taken by one of the governments which are parties to the sanitary union

Honor to Professor Pinard

A few days ago the friends and pupils of Professor Pinard met in the great amphitheater of the medical school to celebrate the twentieth anniversary of his professorship Speeches were made by Professor Landouzy, dean of the medical school, and by Drs Potocki and Segond At the end of the ceremony a commemorative medal was presented to Professor Pinard.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov. 24, 1910

Personals

The Prussian Academy of Science has elected the well-known London surgeon, Sir Victor Horsley, and A Mosso, professor of physiology in Turin, as corresponding members The Bavarian Academy of Science has elected Professor Gruber to regular membership.

Bavarian Antituberculosis Association

November 20, a national association for the suppression of tuberculosis was founded in Munich, the function of which will be a systematic campaign against tuberculosis as a disease of the people The Prince Regent has given the association $1 000 (5 000 marks). At the close of the meeting a tuberculosis museum was opened

Medical Study Trip

The German central committee for study trips plans an excursion to America for 1912 in connection with a visit to the International Hygienic Congress at Washington The journey is to last about six weeks and to cost from $400 (1,650 marks) up, according to the cabin occupied The price includes fare on land and sea and lodging and service while in America.

Illegitimacy from the Social Standpoint

A few days ago one of the speakers at the meeting of the German Morality Society (*Sittlichkeitsverein*) reviewed the subject of the social significance of illegitimacy in the light of statistics He first exhibited the varying degrees to which the evil was present among various nations The Netherlands have 2 5 per cent of illegitimates, Switzerland 4 5, Prussia 9, Saxony 12, Bavaria 14 and Austria above 14 In the same country differences are found Thus North Bavaria has 8 per cent, South Bavaria, 20 Further differences may be noted between town and country Vienna and Munich have quite 30 per cent of illegitimate births, but it must be noted here that the lying in institutions in large cities influence the statistics unfavorably The first factor in the etiology of illegitimacy is the special make up of the population, the proportion of unmarried members of both sexes The probability of illegitimate births is greater, the greater the number of the unmarried, the young, and particularly of young females in the population The Westphalian industrial district, Istria and Dalmatia, in which there is an overplus of men, show only from 3 to 4 per cent of illegitimate births In the Alps and certain agrarian districts in which marriage is commonly entered into late, there is a high percentage of illegitimacy Economic and social conditions also exercise an influence The difference between the social relations and the trade conditions of town and country are not without their effect The observation has been made that four fifths of the illegitimate mothers in the city are from outside and come mostly from simple conditions of life to fall victims to the complicated relations in the great city Half of the illegitimate mothers in the city are orphans (*verwaist*) Finally, ethical conditions, education and race have their effect, thus the Bavarians have the highest rate of illegitimacy.

The speaker also discussed the situation and fate of illegitimate children These children are in greater danger than the legitimate, even after birth, and show a larger ratio of stillbirths In Prussia 34 per cent of illegitimate children die in the first year of life as compared with 18 per cent of the legitimate In Berlin the ratio is 39 to 19 per cent As a matter of fact, the percentage is still more unfavorable and, if the children legitimized in the first year are accounted for, must be placed as high as 46 per cent The causes of this mortality are the unfavorable conditions of care, the frequent change of nurses, and lack of proper support In the first year of life not one half are supported and at the age of 14, only 15 per cent The frequent change of caretakers in later childhood leads to neglect As a consequence of this, criminality is very large among the illegitimate and their industrial training is faulty Finally, the speaker discussed the ethical principles for the protection of the illegitimate Support, titular guardianship and police oversight of the care of the infants are inadequate The only remedy which is of actual value is trade union guardianship (*Berufsvormundschaft*) This can promptly bring the father of the illegitimate child to support it (in Strasburg 59 per cent voluntarily supported their children, while 86 per cent were reached by compulsory measures) This measure also makes possible a proper choice and supervision of the places where the children are cared for, and is financially favorable to the city, while it has also great ethical importance.

Marriages

Charles Pius, M.D., Guadaloupe, Cal., to Miss Eloise Moore of Willows, Cal., November 24.

Luther Raymond Poust, M.D., to Miss Helen M. Alexander, both of Philadelphia, November 30.

Roy Homer Dyer, M.D., Marshall, Mo., to Miss Frances McClure of Houstonia, Mo., November 23.

Emil E. Nussle, M.D., Chippewa Falls, Wis., to Mrs. Jessie Pottle Cox of St. Paul, Minn., December 7.

James Keeley Everhart, M.D., Pittsburg, Pa., to Miss Susan B. Thorley of Harrisburg, Pa., October 22.

Thomas B. Coulter, M.D., Chickasha, Okla., to Miss Hortense B. Rose, Avondale, Cincinnati, November 28.

Deaths

John Cummings Munro, M.D. Harvard Medical School, Boston, 1885; died at his home in Boston, December 6, from recurrent cancer, for which operation had been performed three years before, aged 52.

A Franklin medal scholar and graduate of the Boston Latin School Dr. Munro entered Harvard University in 1877, graduated in 1881, and received the M.D. degree from Harvard Medical School four years later. Establishing himself in general practice in Boston, he soon began to specialize in surgery, developing a rare skill which placed him early in his career in the front rank of the profession. Dr. Munro was associated with the Harvard Medical School as assistant in anatomy from 1889 to 1893; assistant demonstrator of anatomy from 1893 to 1894; assistant in clinical surgery from 1894 to 1895; instructor in surgery, 1896 to 1902, and lecturer in surgery, 1903 to 1905. He was keenly interested in the development of surgery toward which his work was a great contribution. He was surgeon at the Boston City Hospital, 1893 to 1903; consulting surgeon, St. Luke's Home, 1901; special consulting surgeon Quincy Hospital, 1902; consulting surgeon, Framingham Hospital, 1905; surgeon to out-patients, Carney Hospital, 1891 to 1896; and surgeon-in-chief, Carney Hospital since June, 1903. He was a member of the American Medical Association and chairman of the Section on Surgery in 1909; Association of American Anatomists, American Surgical Society, Clinical Surgical Society, of which he was president in 1905; Boston Society of Medical Sciences, Boston Society for Medical Improvement, American Academy of Medicine, Southern Surgical and Gynecological Association, an honorary member of the Vermont Medical Society, the Canadian Medical Association, and the Philadelphia Academy of Surgery.

John C. Da Costa, 1834-1910

John C. Munro, 1858-1910

Dr. Munro belonged to the group of surgeons who went through a long apprenticeship in anatomy as a preparation for surgery. He was noted for his skill in dissection, and for the simplicity and clearness of his demonstration. To this anatomic training was probably due, in a large measure, the technical skill in operation which so distinguished him. He combined, however, with this technical skill, accuracy in diagnosis and remarkable surgical judgment. Entering into surgery at the beginning of the antiseptic period, he quickly acquired a thorough mastery of the details of the method.

Dr. Munro will best be known for his surgical clinic at the Carney Hospital which was instituted in 1903. The establishment of this clinic which carried with it responsibility for the entire surgical service of the hospital, was an important event, as it was the first permanent surgical service to be established in New England. The clinic, under Dr. Munro's guidance, quickly acquired a high rank among the surgical clinics in the country, and, of the surgical clinics in New England, was among the best known and the most frequently visited. His work there served a most useful purpose in various ways. It demonstrated the possibility of doing satisfactory surgery, successful in its results, with simplicity of plant and technic and with a minimum of red tape. In its instruction, it had to do with and reached not so much the undergraduate in medicine as the general practitioner, the worker in the surgical field, the visitor in search of sensible ideas and their application in the field of surgery. At this clinic true charity to the deserving poor was dispensed. The wide-spread abuse of the charity of the medical profession was here combated in the only way in which a successful struggle against it can be made, by refusing charity to those who do not merit it. Dr. Munro not only had strong convictions on this matter, but had the courage to put these convictions into practice in the face of much unfavorable and unjust criticism.

Dr. Munro was well known both in this country and abroad. His contributions to the literature of surgery were numerous and on a variety of subjects. He wrote as he spoke, simply and clearly, and was always conservative and modest in stating his part. His skill as a surgeon was acknowledged by all. Back of it, however, and revealed to but few, were qualities of mind and heart that deserve more admiration than his skill and made the man even greater than the surgeon. Fearless honesty in all things, staunch loyalty to his ideals and to his friends, straightforwardness in his actions, simplicity and cleanliness of life, and modesty as to his self and his achievements were strong characteristics of John Munro. Keen in his observation of men and their methods, he was always charitable in his judgments of both. Traveled, well versed in general literature, appreciative of art in all its aspects, he made a most charming companion. His influence on his fellows was wide and stimulating. A hard worker himself, he incited younger men to action and his hand was ever ready to aid and to encourage them in honest endeavor.

Though naturally undemonstrative and retiring, he was a loyal and devoted friend, and the place he occupied in the affections of the many who knew and loved him for his worth will not be filled.

John C. DaCosta, M.D., a well-known gynecologist of Philadelphia, died at his home, December 6, from pneumonia complicated by arteriosclerosis, aged 76. As a young man, DaCosta was a civil engineer, and was a member of the staff of engineers of the St. Paul and Duluth Railroad for about twenty years. At the age of 40 he took up the study of medicine in Jefferson Medical College, and graduated from that institution in 1878.

Immediately following his graduation, Dr. Da Costa became instructor in his alma mater and was then made demonstrator of obstetrics. He served for more than twenty years as visiting gynecologist to Jefferson Medical College Hospital, and on his retirement several years ago, was made emeritus gynecologist. He was visiting physician to the Lying In Charity Hospital, and visiting gynecologist to St. Agnes Hospital. He was a member of the American Medical Association, president of the Philadelphia Obstetrical Society, and a fellow of the College of Physicians of Philadelphia.

Thomas Gill Nock, M.D. Syracuse (N. Y.) University, 1883; formerly a member of the American Medical Association; a member of the Medical Association of New York and New England Railway Surgeons; Society of the State of New York; mayor of Rome in 1904 and 1905, and for six years a member of the fire and police commissioners; three terms coroner of Onedia County; a member of the board of managers of the Utica State Hospital, and local surgeon to the New York Central Railroad Company; was found dead at his home, November 28, from strangulation, aged 51. Dr. Nock had been in ill health for several years, and it is believed that while mentally irresponsible, on account of ill health, he committed suicide.

John Frederick Haller, M.D. University of Buffalo, N. Y., 1888; a member of the Medical Society of the State of New York; consulting gynecologist to Jamaica Hospital; visiting physician to the Bushwick Hospital for Children; examining physician of the Department of Charities for Brooklyn; one of the organizers of the Swedish Hospital; a surgeon of volunteers during the Spanish-American War, attached to the Tenth U. S. Cavalry; died at his home in Brooklyn, December 3, from pneumonia, aged 48.

Abram Brothers, M.D. College of Physicians and Surgeons, New York City, 1884; a member of the American Medical Association, New York Academy of Medicine, and New York Obstetrical Society, founder and once president of the Eastern Medical Society; visiting gynecologist to the New York Post-Graduate and Beth Israel Hospitals; associate professor of Gynecology in the Post-Graduate Medical School; died at his home in New York City, October 13, from diabetes, aged 49.

Julius Pohlman, M.D. University of Buffalo, N. Y., 1883; a member of the Medical Society of the State of New York; formerly assistant in the Museum of Natural Sciences, Buffalo, and later director; lecturer in physiology in his alma mater from 1883 to 1886, and from that time until 1898, professor of physiology; a specialist in diseases of the eye; elected general secretary of the German Society of Naturalists in 1888; died at his home in Buffalo, December 6, aged 62.

Josiah Nichols Woodward, M.D. Dartmouth Medical School, Hanover, N. H., 1880; a member of the New Hampshire Medical Society, and a member of the staff of the Nashua Hospital; city physician of Nashua for three years; a member of the board of health for four years; a member of the common council, and a member of the legislature in 1893 and 1909; died at his home in Nashua, November 28, from abscess of the liver, aged 54.

Benjamin Franklin Haskins, M.D. Bellevue Medical College, 1873; of La Junta, Colo.; formerly a member of the American Medical Association; a veteran of the Civil War; secretary for many years of the school board of Alamosa and La Junta, Colo.; division surgeon of the Denver and Rio Grande Railroad at Alamosa; and consulting surgeon to the Santa Fe Hospital, La Junta; died in Washington, D. C., October 4, aged 62.

Frederick Francis Kelly, M.D. New York University, New York City, 1888; a member of the Prince Edward Island Medical, Maritime Medical, and Canadian Medical Associations; a member of the city council of Charlottetown, and once mayor of the city; a member of the staff of the Charlottetown Hospital; died in that institution, June 5, from mastoid disease, aged 44.

William McAfee Hanna, M.D. University of Louisville, 1862; of Henderson, Ky.; assistant surgeon of Colonel Basil Duke's regiment, C. S. A., during the Civil War; formerly a member of the American Medical Association; for several years a member of the Henderson Board of Health; died in Letcher's Hospital, Henderson, November 28, from cerebral hemorrhage, aged 73.

Clarence W. Erwin, M.D. Medical College of the State of South Carolina, Charleston, 1880; of Erwinton, S. C.; corresponding secretary and treasurer of the Christian Church of South Carolina for twenty-two years; prominent as a planter and physician; died at the home of his brother in Allendale, November 23, from nephritis, aged 53.

William Allen Hubbard, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1876; formerly hospital steward in the Freedman's Bureau, Pine Bluff, Ark., and later apothecary in the U. S. Marine-Hospital Service; later a practitioner of Billerica, Mass., and superintendent of Winchester Hall; died at his home in Boston, Oct. 22, 1909, aged 66. (Bu)

Julien E. Hequembourg, M.D. Rush Medical College, 1882; of Chicago; a member of the American Medical Association, and Physicians' Club of Chicago; attending physician to St. Joseph's Hospital, and the Daily News Sanitarium for Babies; died suddenly while making his rounds in St. Joseph's Hospital, Chicago, December 8, from heart disease, aged 54.

Oliver A. Harrison, M.D. University of Louisville, Ky., 1882; a member of the Mississippi State Medical Association; local surgeon for the Queen and Crescent System; who had been incapacitated from active service since last winter when he fell on the ice, fracturing his right femur; died at his home in Meridian, December 3, aged 65.

Montraville McHenry, M.D. University of Vermont, Burlington, 1878; a member of the Medical Society of the State of Pennsylvania, and a member of the House of Delegates from the Columbia County Medical Society at the 1910 meeting; died at his home in Benton, December 1, from cerebral hemorrhage, aged 74.

John H. King, M.D. University of Wooster, Cleveland, 1872; formerly of Butler and Saxonburg, Pa., and a member of the city council and school board of the latter place; died, November 26, near his home at Houseville, from injuries and exposure following an accidental fall over an embankment, aged 67.

Benjamin Williams, M.D. Medical School of Maine, Brunswick, 1864; assistant surgeon of the Eighth Maine Volunteer Infantry during the Civil War; and later state commander of the Grand Army of the Republic; twice mayor of Rockland, Me.; died in Prospect Harbor, Me., November 27, aged 75.

Francis Howe Munroe, M.D. New York Homeopathic Medical College, New York City, 1886; a member of the staff of St. Mary's Hospital, Passaic, N. J., and the Essex County Homeopathic Hospital; died at his home in Newark, N. J., November 29, from cerebral hemorrhage, aged 48.

Patrick Henry McRaven, M.D. Missouri Medical College, St. Louis, 1878; formerly of McClure, Ill., but for a few months a resident of East St. Louis; at one time a member of the staff of the Anna State Hospital; died at his home in East St. Louis, November 21, from pneumonia, aged 58.

Andrew Jackson Sibley, M.D. University of Tennessee, Nashville 1894; a member of the State Medical Association of Texas; one of the board of censors of the Seventh Councilor District Medical Society; died at his home in Creedmoor, June 29, from cerebral hemorrhage, aged 45.

Wear F. Armstrong, M.D. Southwestern Homeopathic Medical College, Louisville, Ky., 1899; a member of the American Medical Association; died at his home in Henderson, Ky., September 12, during an injection of antistreptococcus serum for an infected operation wound, aged 36.

James J. McKone, M.D. Bellevue Medical College, 1887; a member of the American Medical Association; surgeon to St. Joseph's Hospital, Tacoma; acting assistant surgeon, U. S. P. H. and M.-H. Service; died in his apartments in Tacoma, November 27, from pneumonia, aged 47.

Alonzo R. Todd, M.D. Jefferson Medical College, 1880; of Ocean Grove, N. J.; formerly of Baltimore; a member of the Ocean Grove Board of Education; died at the Jefferson Hospital, Philadelphia, November 25, after an operation for the removal of gall-stones, aged 55.

Joel Hill, M.D. College of Physicians and Surgeons, Baltimore, 1880; a member of the Medical Society of the State of North Carolina, and Association of Surgeons of the Southern Railway; died at his home in Lexington, November 22, aged 55.

Harold B. Marchant, M.D. McGill University, Montreal, 1910; of Victoria, B. C.; died at the Terminal City Hospital, November 17, from injuries received while leaving the Britannia Mine, Howe Sound, the day before, aged 28.

Wash Miller, M.D. University of Louisville, 1866; of Winchester, Ky.; for many years president of the Citizens National

Bank in that city; died at the Brown-Proctoria Hotel, Winchester, October 27, from angina pectoris, aged 71.

William Perry Bennett, M.D. Washington University, St. Louis, 1844 or 1845; a well known physician and clergyman of Daviess County, Ky.; died at the home of his son in Utica, October 29, from senile debility, aged 87.

Edward G. Cannon, M.D. Louisville; a veteran of the Mexican War; at one time a circuit rider in southeastern Kentucky; for ten years a resident of Nome, Alaska; died in that place, November 21, from pneumonia, aged 87.

John Henry Arnold (years of practice, Arkansas); for many years a practitioner of Indian Territory; a veteran of the Civil War; died at his home near Henderson, Okla., December 1, from bronchopneumonia, aged 62.

Samuel A. Huffman, M.D. St. Louis College of Physicians and Surgeons 1896; formerly president of the Macoupin County (Ill.) Medical Society; died at his home in St. Louis, November 24, from heart disease.

Robert G. Simpson, M.D. Medical College of Ohio, Cincinnati, 1876; of Modesto, Cal.; formerly of Rising Sun, Ind.; died at the home of his nephew in Modesto, December 1, from heart disease, aged 64.

John M. Sweezy, M.D. Cincinnati College of Medicine and Surgery, 1860; of Cross Plains, Ind.; died in the Madison Sanitarium, Versailles, Ind., November 29, from senile dementia, aged 81.

Charles Butler Stiles, M.D. University of Edinburgh, 1887; died at his home in Hillview, N. Y., November 19, from injuries received from a fall over a steep embankment, aged 49.

Everett Grover Cleveland Snyder, M.D. University of Louisville, 1910; an intern in St. Vincent's infirmary, Little Rock, Ark.; died in that institution, October 17, from typhoid fever, aged 26.

George Frederick Emery, M.D. Queens University, Kingston, Ont., 1889; an eye, ear, nose and throat specialist of Ottawa; died at his home, November 23, from disease of the intestines, aged 43.

Thomas Rhoades Austin, M.D. Eclectic Medical Institute, Cincinnati, 1877; a veteran of the Civil War; died at his home near Neosho, Mo., November 12, from paresis, aged 69.

John Henry Bass, M.D. Louisville, 1859; surgeon in the Confederate service during the Civil War; died at his home in Abilene, Tex., November 14, from tuberculosis, aged 71.

F. Emile Gilbert, M.D. Laval University, Quebec, 1900; a member of the Société Médicale de Quebec; died at his home in Fraserville, Que., October 15, from pneumonia, aged 36.

Albert E. Auringer, M.D. Hahnemann Medical College, Chicago, 1888; of Mendota, Ill.; died December 4, while making a professional call, from cerebral hemorrhage, aged 53.

John E. McCune, M.D. Ohio, about 1850; died at the home of his niece in Plain City, Ohio, October 30, from senile debility, aged 84.

Pharmacology[1]

ANADOL MISBRANDED ?

The United States District Attorney in Chicago has filed information against C. G. Wheeler of the Wheeler Chemical Works, Chicago, for misbranding "Anadol." This nostrum, our readers will remember, was exposed by the Association chemists in THE JOURNAL, May 21, 1910, p. 1704. Anadol is one of those vicious mixtures which physicians are asked to prescribe, and which contain the dangerous, though if rightly used valuable, drug, acetanilid; yet there is no statement in the advertising matter or on the label to indicate its actual composition. Happily such preparations are gradually becoming extinct, and the Council on Pharmacy and Chemistry, and the Chemical Laboratory of the American Medical Association are to be credited, in great part at least, for this change in conditions. Of course, our exposé of this nostrum did not prevent its being advertised to, and prescribed by, those physicians who prefer to depend on the "literature" of proprietary promoters. But this action of the government will certainly put an end to this product, so far, at least, as interstate commerce is concerned.

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

TABLETS OF BISMUTH, OPIUM AND PHENOL

A Second Examination Which Illustrates the Limitations of Tablet Compounding

W. A. Puckner and W. S. Hilpert

More than two years ago the examination of tablets of bismuth, opium and phenol was taken up in the Association laboratory to determine the reliability of pharmaceutical preparations of complex formulas, more or less difficult to prepare. The result of this examination, published in THE JOURNAL, July 25, 1908, p. 330, showed that the tablets sold by different firms contained amounts of phenol ranging from 72.65 per cent. down to 12.66 per cent. of the amount the tablets were claimed to contain. In discussing this discrepancy three questions may be asked: 1. Are these supposedly reputable firms deliberately selling these products below standard? 2. Are these firms unable to determine the quality of their product? 3. Do these firms merely neglect to determine the composition of the finished product? In other words are these firms dishonest, incompetent, or merely negligent? Considering the standing of the firms named in the report one would hesitate to say that these discrepancies were due either to dishonesty or to incompetence and would be inclined to take the more charitable view of negligence.

Two years having elapsed and the report of the laboratory having been given the widest publicity, it would seem that if these firms were ignorant of the real composition of their product at the time the examination was made and published, they would by this time have had ample opportunity to correct the matter, and either to have brought the products up to the claim or else to have discontinued their sale.

To determine whether the discrepancies pointed out in the report referred to could be ascribed to ignorance and whether the firms had made any effort to improve the quality of the products, specimens of these tablets as sold by each of the firms concerned in the first report were again purchased from one of the large wholesale drug houses and their phenol content again determined.* The following table gives the result of this examination:

Manufacturer.	Per cent. phenol according to formula on label.[1]		Per cent. phenol found.		Amount found expressed as per cent. of amt. claimed.[2]		Percentage of variation (plus or minus) between 1908 and 1910 findings.
	1908	*1910*	*1908*	*1910*	*1908*	*1910*	
Hance Bros. & White	8.45	8.19	1.85	2.80	21.89	34.19	+ 12.30
W. S. Merrell Chem. Co...	6.30	6.91	3.08	3.98	48.89	57.59	+ 8.70
H. K. Mulford Co.	1.72	1.70	0.90	1.08	52.34	63.53	+ 11.19
Parke, Davis & Co.......	6.08	5.42	...	2.54	70.23	46.86	—23.37
Sharp & Dohme	8.41	8.49	6.11	4.43	72 65	53.39	—19.26
F. Stearns & Co.	7.27	7.51	1.93	1.74	26.55	23.17	— 3.38
Truax, Greene & Co.......	10.03	10.00	1 36	2.81	13.69	28.09	+ 14.40
H. K. Wampole & Co.......	8.98	8.80	3.49	4.73	39.31	53.75	+ 14.44
W. R. Warner & Co.	12.08	12.15	1.53	1.49	12.66	12 27	— 0.39

1. These figures were calculated from the claimed phenol-content of each tablet and the average weight of the tablets found.

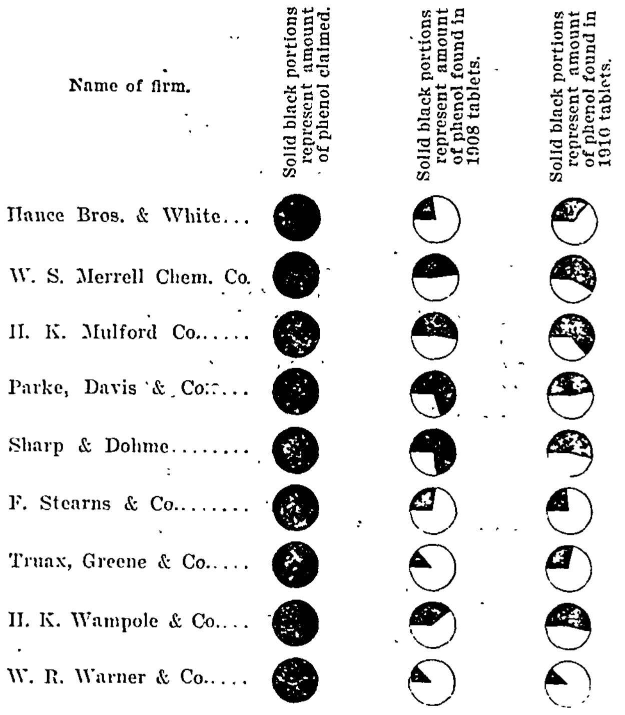
2. These figures were calculated from the percentage of phenol claimed (Column 1) and the percentage found (Column 2).

From the above results it is seen that at the present time the phenol-content of the tablet now ranges from a maximum of 63.53 per cent. down to a minimum of 12.27 per cent. of that claimed on the label. The products of some of the firms have improved somewhat, while the products of others are worse than they were two years ago. On the whole, it seems that many of the firms still sell these products without being greatly concerned as to their composition. But one firm, whose product contains nearly two-thirds (⅔) of the amount of phenol claimed, the H. K. Mulford Co., appears to have considered the past report. The trade package now bears the following legend: "The amount of phenol in this tablet on account of its volatile nature is approximate." It would seem then, that, of the three alternatives suggested, the one ascribing this discrepancy to negligence must be discarded and the profession must decide whether it is to be attributed to incompetence or dishonesty.

---

* For method of analysis see "Method B," in "Reports of the Chemical Laboratory of the American Medical Association," 1, 28.

Editorial Note:—The findings of the Association chemists are not creditable to the pharmaceutical manufacturers concerned. The question asked is a serious one. Regarding at least most of the firms the charge of incompetence would hardly hold, since they employ chemists who are men of standing and are known to be entirely competent to control the manufacture of their products. To say that these firms are dishonest in the matter is a serious charge and no one will believe for a moment that they deliberately used a deficient amount of drug for the sake of saving a few paltry cents in the manufacture of these tablets. We would be inclined to take the view that these firms have little respect for physicians who use such complex mixtures; that, though producing, as a general rule, reliable and honest medicines they believe that in the case of products such as these, scientific accuracy is a waste of time. Perhaps they are right. At least, this should serve as a lesson to physicians who are inclined to use complex, ready-made formulas of this kind and persuade them to write individual prescriptions whose correct compounding by competent pharmacists may be depended on



The above chart presents the findings of the Association chemists in a graphic form and shows the great discrepancies between the claims made for the tablets and the actual facts. The solid black portions represent the phenol-content. In the first column is given the phenol content claimed by the manufacturer; in the second column is shown the actual phenol-content found in the tablets purchased in 1908, while the third column represents the phenol-content as found in the tablets purchased in 1910.

Correspondence

Priority in a Method of Prevention of Perforation in Submucous Resection

To the Editor:—*Nihil novum sub sole!* In to-day's mail I received The Journal of November 19 containing (p. 1785) an article of mine entitled "An Original Method for Prevention of Perforation in Submucous Resection." In the same mail I received, from its author, Dr. William R. Murray of Minneapolis, a reprint of an article from the *St. Paul Medical Journal* of January, 1907, on "The Submucous Resection of the Nasal Septum for the Correction of Septal Irregularities," on page 4 of which I find this marked paragraph: "For this reason I prefer to make the incision through the cartilage a little posterior to the primary incision through the muco-perichondrium, if the character of the deviation will allow it, in order that the membrane on the convex side may cover any such accidental puncture of the opposite membranes."

The assumption of originality in my article was made in good faith. I evolved this method for my own use, absolutely without any knowledge that Dr. Murray had worked out practically the same principle in 1907. Now that he has so kindly and promptly brought his article to my attention, I gladly avail myself of this opportunity of giving him due credit for priority.

Richard M. Nelson, M.D.,
Colon Hospital, Cristobal, C. Z.

Thanksgiving Celebration of American Physicians in Vienna

To the Editor:—Many of the American physicians studying in Vienna decided to celebrate Thanksgiving Day in a befitting manner. Semmering with its beautiful surroundings offered them the greatest attraction and the Pension Alpenheim was secured for this festive occasion. Among those present were:

Dr. and Mrs. J. J. Durand, Atlantic City, N. J.
Dr. and Mrs. Charles A. Drake, Norwich, N. Y.
Dr. and Mrs. B. F. Ochs, New York.
Dr. and Mrs. E. C. Dalton, Valdez, Alaska.
Dr. and Mrs. S. M. Rinehart, Pittsburg.
Dr. and Mrs. A. C. Tingdale, Minneapolis.
Dr. and Mrs. Milton A. Shlenker, New Orleans.
Dr. Lee Edwards, Toronto, Canada.
Dr. F. O. Kershner, Clinton, Iowa.
Dr. George I. Barber, Chicago.
Dr. E. C Wrightsman, South Chicago, Ill.
Dr. Joseph Schwarz, Mobile, Ala.

The physicians and their wives entered into the spirit of the occasion with great enthusiasm. Mrs. Lovasy, the hostess, announced dinner at 2 p. m., and surprised all with the banquet table dressed in the American colors. Flags and bunting and the beautiful ladies who graced the occasion made a picture which aroused the American patriotism of all present. After turkey, cranberry sauce and plum pudding were served, the health of the president and of the kaiser were toasted, and this was followed by a dance.

M. A. Shlenker.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TREATMENT OF ACIDOSIS—CASOID FLOUR

To the Editor:—1. Is the presence of acetone and diacetic acid in the urine an infallible sign of severe acidosis? What do you think of the following case? In a married woman, aged 28, whose mother died of diabetes, diabetes was discovered about a year and a half ago. The patient was given Fowler's solution by her physician, but never put on a strictly starch-free diet. I saw her first Oct. 1, 1910, when the condition was as follows: Twenty-four-hour amount of urine, 50 ounces; 3.4 per cent. of sugar, no albumin, no casts. Sodium nitroprussid test for acetone strongly positive; ferric chlorid test for diacetic acid also very strongly positive. General condition of patient was very good; she felt fine and was not easily fatigued. I put her on Forchheimer's test diet and within two weeks the urine was entirely free from sugar, but there was still the acetone and diacetic acid, although I gave her 30 grains of sodium bicarbonate three times a day. Still she feels perfectly well and vigorous. On November 1 I started giving her two ounces of wheat bread daily. Sugar at once appeared in the urine, about 0.45 per cent. November 7 I changed to three ounces of bread made from gluten flour (40 per cent. of protein), allowing two ounces of oatmeal also. Sugar remains about 0.45 per cent. Twenty-four-hour amount has ranged from 48 to 65 ounces; specific gravity never above 1.030, acetone and diacetic acid constantly present in large amounts, and patient feeling perfectly well. Thirty grains of sodium bicarbonate, three times a day, has been continued from the start. What prognosis would you give? What treatment would you advise?

2. What do you know about "casoid flour," made in England, sold by T. Leeming, 43 Warren Street, New York, and represented as a starch-free flour?

H. M. M.

ANSWER.—1. Oxybutyric acid, diacetic acid and acetone are known as the acetone bodies. According to present chemical opinion they are largely derived from the fatty acids and appear in the blood and in the urine when large amounts of fats are metabolized in the body. Being acid, they reduce the alkalies of the body and produce the condition known as acidosis. In many cases the formation of these acetone bodies is due to lack of food, without any failure to utilize sugar properly. These bodies also appear in diabetes when sugar formed from ingested carbohydrates, or from the proteins of the foods or tissues, cannot be utilized in sufficient quantity to maintain nutrition. When there is no failure to utilize sugar, and in mild cases of diabetes, the administration of carbohydrates will prevent the formation of these acetone bodies. Acidosis produced by the acetone bodies may be either of a low grade, in which case it does not seriously affect the prognosis, or it may be extreme, in which case it portends the oncoming of diabetic coma. In the case described it would be impossible to give a reliable prognosis without quantitative measurements of the acidosis by determination of the amount of acetone bodies and of the acidity and ammonia content of the urine. Inasmuch, however, as the patient does not seem to be materially affected by the acidosis, a relatively favorable but guarded prognosis should be given. The treatment has evidently been correct and should be continued. An attempt, however, to find a carbohydrate that can be utilized by the patient would be desirable. We would suggest the trial of more oatmeal and less flour. It is evident that gluten flour, with 40 per cent. protein, still contains a very large proportion of carbohydrates. Potatoes might also be tried as a source of utilizable carbohydrate.

2. Analyses of casoid flour have shown it to be practically free from carbohydrates. The statement that it is entirely starch-free has not been true in the past, and on account of this unsubstantiated claim it has not been accepted by the Council. The casoid biscuit, or crackers, contain an appreciable, although small, amount of carbohydrates. Casoid flour, however, is not a gluten flour, but contains casein.

A CONVENIENT STAIN FOR THE SPIROCHÆTA PALLIDA

To the Editor:—I notice that in THE JOURNAL (December 10, page 2081) you give the Giemsa stain as an effective method for demonstrating *Spirochæta pallida*. While the results obtained with the Giemsa mixture are perfectly satisfactory, the time required renders it inconvenient. The following method, a description of which I published in 1903 (*Med. News*, 1903, lxxxiii, 248), gives the same results as the Giemsa and requires only ten minutes.

Smears of serum from the lesion are dried and fixed in strong methyl alcohol for two minutes. They are then stained for eight minutes, as follows: About 0.5 c.c. of a 1 to 1,000 aqueous solution of Grübler's eosin W G is placed on the surface of the smear. An approximately equal quantity of a 1 to 400 aqueous solution of Grübler's azure I is squirted on the slide from a pipette bottle and thoroughly mixed with the eosin. The exact quantities are unimportant. The staining mixture precipitates somewhat and should have a predominantly blue color. After eight minutes the slide is washed off in a strong stream of water. It will then be found to be stained perfectly as with the Giemsa method, and the *Spirochæta pallida*, if present, can be easily demonstrated.

This stain has been used by me and by my pupils for the past eight years as a general blood-stain, especially suitable for malarial parasites. The staining can be very considerably shortened, and for general purposes it is occasionally an advantage to use azure II, which contains some methylene blue, instead of the azure I.

FRANCIS C. WOOD, New York.

PRICES OF FOREIGN PUBLICATIONS

To the Editor:—Kindly let me know the subscription price and address of the *Presse Médicale* of Paris and the *British Medical Journal* of London.

H. E. RANDALL, Flint, Mich.

ANSWER.—*British Medical Journal*, 429 Strand, London, England, $8 a year, including postage; *Presse Médicale*, 120 Boul. St. Germain, Paris, $3.75 a year, including postage.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Dec. 10, 1910.

Eber, A. H., M.R.C., December 1, reported for temporary duty at Fort Dade, Fla.

Patterson, R. F., D.S., December 3, reported for temporary duty at Fort Thomas, Ky.

Stallman, George E., D.S., December 1, returned to Fort Sam Houston, Texas, from temporary duty at Fort McIntosh, Texas.

Halliday, Charles H., M.R.C., December 3, left Fort Fremont, S. C., on ten days' leave of absence.

Bowen, Albert S., lieutenant, December 3, left Fort Snelling, Minn., on ten days' leave of absence.

Sherwood, John W., M.R.C., December 5, reported for temporary duty at Fort Strong, Mass.; left Fort Andrews, Mass., same date.

Weston, Henry R., M.R.C., December 5, left Fort Strong, Mass., on thirty days' leave of absence.

Long, Charles J., D.S., December 9, reported for duty at Fort Andrews, Mass.

Trinder, J. H., M.R.C., December 8, reported for duty at Fort Jay, N. Y.

Medical Corps, U. S. Navy

Changes for the week ended Dec. 10, 1910.

Parker, E. C., surgeon, ordered to the naval academy.

Stuart, A., surgeon, detached from the naval hospital, Boston, and directed to continue duty at the navy recruiting station, Hartford, Conn.

Olson, G. M., asst.-surg., transferred to the retired list from Dec. 2, 1910; ordered home.

Randall, J. A., P. A. surgeon, and Brown, H. L., P. A. surgeon, detached from the naval hospital, Olongapo, P. I., and ordered home.

Thomas, G. E., asst.-surg., detached from the naval hospital, Canacaco, P. I., and ordered to duty at the naval hospital, Olongapo, P. I.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Dec. 7, 1910.

Carmichael, D. A., surgeon, leave of absence for nineteen days from Nov. 15, 1910, amended to read eighteen days from Nov. 15, 1910.

White, J. H., surgeon, granted twenty days' leave of absence from Dec. 2, 1910, without pay.

Williams, L. L., surgeon, granted seven days' leave of absence from Dec. 2, 1910, under paragraph 189, Service Regulations.

Wertenbaker, C. P., surgeon, detail to represent the service at the meeting of the Seaboard Medical Association to be held in Kinston, N. C., Dec. 6-8, 1910, revoked on account of sickness.

Lavinder, C. H., P. A. surgeon, detail to represent the service at the meeting of the Seaboard Medical Association to be held in Kinston, N. C., Dec. 6-8, 1910, revoked on account of sickness.

Gwyn, M. K., P. A. surgeon, granted seventeen days' leave of absence from Dec. 24, 1910.

Creel, R. H., P. A. surgeon, relieved from duty in the bureau and directed to report to the director of the hygienic laboratory.

McKeon, F. H., P. A. surgeon, relieved from duty at Manila, P. I., and directed to proceed to San Francisco and wire arrival.

De Valin, Hugh, P. A. surgeon, directed to proceed to Chicago and report to the medical officer in command for temporary duty.

Ridlon, J. R., asst.-surg., granted fourteen days' leave of absence from Dec. 21, 1910.

Miscellany

Ehrlich's Instructions Concerning Salvarsan (606).—Under the date of Oct. 25, 1910, Dr. Ehrlich has issued a circular letter in which he gives his latest ideas as to the methods of administering "606." He says that over 40,000 ampullas of the preparation have been distributed and reports have been received concerning its use. These reports have pretty well settled the dose, indications and contraindications. It should not be used in cases of atrophy of the optic nerve, but may be applied in other syphilitic diseases of the eye, especially gummatous iritis, but should not be used in severe diseases of the nervous system or of the heart and blood-vessels. The first phase of the trial may, therefore, be considered as closed. We now begin the second period, which concerns the permanent results of the remedy. These will depend on a series of circumstances, especially the size of the dose and the method of application, and second, the nature of the disease. The permanent results will be greater, the more decided the first therapeutic impressions. This, naturally, increases with the size of the dose and the rapidity of absorption. From this standpoint, the most efficient methods are (1) intravenous injection; (2) intramuscular injection of an alkaline solution; (3) the markedly irritating acid injection, and (4) the so-called neutral emulsions. He considered that in the first phase the greatest freedom should be allowed to the experimenters in the choice of a method, as only in this way, by a comparison of results, could an idea of the relative value of the different methods be obtained quickly. But it has already been established that the methods most applied, either the intramuscular or subcutaneous injection of the neutral emulsion, have less value as far as permanent results are concerned. This may depend on the fact that it is more difficult to prepare these emulsions with absolute uniformity and minuteness of subdivision, which results in a variability in the rapidity of absorption; and in many instances the therapeutic effect by this method was not sufficiently intensive to secure in general the sterilization or destruction of the spirochete. The intravenous injection gives better results. The technic is simple and in a proper selection of cases is free from danger, and for many patients much more pleasant. There have been over 1,000 cases already treated by the intravenous method. As an intravenous injection, Alt injects at least 0.3 to 0.4 or 0.5 gm., some give still larger doses, 0.7 to 0.8 gm. The intravenous injection can be repeated after two or three weeks, according to the need of the case, if the curative effect of the first injection is not complete and the Wassermann reaction is still positive. So far, indications of a hypersusceptibility have not appeared, although in many instances intravenous injections have been employed two, three, four or five times. Ehrlich says that the reports that have reached him indicate that the intravenous method deserves prominence over the other methods, especially the subcutaneous. He does not overlook the fact that this method will meet certain technical difficulties in ordinary practice, still it is important in the interest of patients to secure at once the most effective treatment. The intravenous method is therefore recommended by Ehrlich, at least for hospitals and clinics. The things to be especially considered are the following: 1. The disease should be put under treatment as promptly and early as possible, as it generally occurs in robust young individuals. They should be treated with at least 0.5 intravenously. In addition, it would be advisable, in the interest of actual sterilization, to employ an energetic local treatment, extirpation, cauterization or some of the other methods used. 2. In diseases of the central nervous system and the circulatory apparatus, so far as these are really suited to treatment, the greatest caution is advised and small doses, 0.2 to 0.4, should be used, but whether in these cases the intravenous method does not deserve the preference over the forms of application heretofore used, has not yet been sufficiently determined. Ehrlich, therefore, advises that in the future, as far as possible, the intravenous injection should be used.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Legal Value of Vital Statistics

Mr. W. J. V. Deacon, statistician of the Kansas State Board of Health, in the *Journal of the Kansas Medical Society*, November, 1910, discusses vital statistics, with special reference to their legal and social value. As most discussions of this question relate to the medical and sanitary side of registration, this paper is especially deserving of attention by physicians. While too much cannot be said on the value of properly recorded and tabulated vital statistics as a means of "sanitary bookkeeping" and as a stimulus to hygienic reforms, it must be remembered that the recording by the state of births, deaths and marriages is of quite as much importance to the lawyer, the business man and the average citizen as it is to the sanitarian. Mr. Deacon lays special emphasis on the necessity of presenting the facts brought out by registration of vital statistics to the attention of the public and keeping these facts constantly in the foreground. He says:

"It has been said that vital statistics can make disease centers as obvious and as offensive as the smoking nuisance. They will not do this, however, unless they are advertised. The compilation of vital statistics as a matter of history is worse than useless and does not begin to furnish an adequate return for the time, money and effort put in their compilation. To be of real value, vital statistics must be a guide to our public health officials and to every public spirited physician, in the campaign against disease. That the collection and publication of vital statistics is of great importance is a well recognized fact. In international statistics, practically every well known European state is represented. In addition, I might mention such countries as New South Wales, Tasmania, New Zealand, Ceylon, Jamaica, Finland, Roumania, Bulgaria, Japan and Chili. The United States, as a whole, is not represented in international vital statistics."

Mr. Deacon gives three important reasons for recording births and deaths. These are: first, protection of the rights of the individual and of the community; second, the protection of the health and lives of the people; third, the knowledge of the movement of the population. After pointing out that statistical officers are usually under the direction of state or city boards of health and that, for this reason, the legal and social importance of vital statistics has been lost sight of, Mr. Deacon says:

"The interest of lawyers in this movement is generally because the very nature of their profession causes them to appreciate more quickly the disadvantages and financial hardships that individuals so often suffer, but this, like the interests of the physicians from a sanitary standpoint is not based alone on the professional interest of individual practitioners, though it is true that an orderly and authentic system of recording births and deaths would greatly facilitate legal procedure. The greatest benefit will result to the people themselves and not to any one profession."

Mr. Deacon gives seven provisions which should govern the registration of deaths:

1. Deaths must be registered immediately after their occurrence.
2. Certificates of death must be recorded.
3. Burial or removal permits are essential to the enforcement of the law.
4. Efficient local registrars are necessary.
5. The central registration office should have full control of the machinery and its rules should have the effect of law.
6. The transmission and preservation of returns should be provided for.
7. Penalties should be provided and enforced.

Mr. Deacon considers that one of the fundamental purposes of the proposed national department of health is the collection, compilation and use of vital statistics and repeats the three economic reasons given by Allen for the establishment of such a department. These are: first, to enable society to increase the percentage of exceptional men of each degree, many of whom are now lost through preventable accidents; and also to increase the total population; second, to lessen the cost of sickness; third, to decrease the amount spent on criminality that could be traced (if there were properly filed and reliable figures from which to draw conclusions) to overcrowded unwholesome and unhygienic environment.

In discussing the influence of vital statistics on social problems, he says:

"Whenever the term 'statistics' is applied to social facts it suggests action, social control of future contingencies, mastery of the facts whose actions are chronicled. The object of gathering social facts for tabulation is not to gather material for future historians, they are to be used in shaping future history. They are facts collected with a view to improving social vitality, to raising the standard of life and to eliminating permanently those forces known to be destructive to life. Unless they are used in this way they are of interest only to the historian. No city or state can afford to erect a statistical office to serve as a curiosity shop."

This portion of the paper concludes with an arraignment of Kansas which ought alone to be sufficient to secure the enactment of a proper registration law in that state at the next meeting of the legislature:

"Kansas, poor old Kansas! Bleeding Kansas! Bleeding money, wheat and corn at every pore. 'Tis said. A land of smiling sunshine, of winding streams, where you have but to tickle the soil to make it laugh a harvest. A land dotted with school houses and growing towns and villages, called cities by divine right of prophecy. A *land of* pigs given to adipose, of sleek cattle, of strong horses, of handsome women, of bouncing babies, of homely, rugged men. A land where no one dies except through accident or over eating. Poor, bleeding Kansas cannot afford to pay 25 cents to register those bouncing babies and, while for years they have duly registered their fine pigs, their cows and their horses at an expense of from 50 cents to $10.00 each, they deny to the future citizen, the potential fathers and mothers of this great republic, the right of registration, the establishment of their legal birthright, for the pitiful sum of 25 cents.

"'Have you a little fairy in your home?' If you have she is not registered No human eye can pierce the future and while you by study, industry and thrift may think to leave that 'fairy' far above the reach of the breakers of misfortune, who knows what may arise in the future to require that little one to prove herself your child, your heir and the right to exercise those sovereign rights of citizenship to which estate the little one has been born, and in which rights you to day think her secure

'The state owes to every citizen the right that the three principal events in the life of each of them shall be a matter of public record, and these three events are the birth, marriage and death This state owes it to you to maintain these records, a duty it has shamefully neglected"

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR JOHN H BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course]

Fifth Month—Second Weekly Meeting

I Hyperemias of the Skin

Erythema Hyperemicum Erythema caloricum, e solare, e venenatum, e ab igne, e. traumaticum Symptoms and treatment

Erythema Intertrigo Chafing

II Inflammations

Erythema Multiforme Etiology Symptoms Constitutional symptoms, visceral manifestations, varied lesions.

Erythema Nodosum· Etiology, symptoms

Erythema Scarlatinoides Symptoms and diagnosis

Pellagra Etiology Symptoms Disturbances of gastrointestinal and cerebrospinal systems Cutaneous lesions—three stages—congestion, thickening and pigmentation, atrophic thinning

Urticaria Etiology Symptoms Varied lesions Urticaria papulosa, u gigans, u bullosa, u hemorrhagica, u perstans, u factitia Treatment

Angioneurotic Edema Symptoms Diagnosis Treatment

Eczema Acute, subacute and chronic
- Eczema erythematosum, lesions, usual locations
- Eczema papulosum lesions, locations, course
- Eczema vesiculosum, lesions, locations, course
- Eczema pustulosum, lesions, locations
- Eczema rubrum and e squamosum, secondary conditions

Regional Eczema

Diagnosis Redness, papule, vesicle, or pustule, discharge, crusts and scales, thickening and infiltration, itching and burning Differentiate from scabies, herpes, dermatitis, impetigo contagiosa, sycosis, psoriasis, lichen planus

Society Proceedings

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Nineteenth Annual Meeting, held at Richmond, Va , Oct 31–Nov 4, 1910

The President, Col Joseph K Weaver, N G , Pa , Norristown, in the Chair

Officers Elected

The list of officers elect was published in The Journal, November 5 page 1656 Milwaukee was selected as the place of meeting for 1911

Reports of Officers

Major Herbert A Arnold, N G , Pa treasurer, reported the largest number of paid up members in the history of the organization—1 445—and that the balance in his hands was $5,826 41, or $129 09 more than for the previous year

Major Charles Lynch, M C , U S Army, secretary and editor, explained that the loss in advertising receipts was due to the acceptance of no advertisements except those approved by the Council on Pharmacy and Chemistry of the American Medical Association

Department of Public Health

At the business meeting resolutions were adopted favoring the passage of Senate Bill 6049, now pending, or essentially similar legislation having for its object the establishment of a national department of health, of equal dignity and power with other departments of the government, having at its head a secretary of public health, a cabinet officer

Pay for Organized Militia

On motion of Col L Mervin Maus, M C , U S Army, a resolution was adopted asking Congress to provide that medical officers and members of the hospital corps of the organized militia receive an annual pay to the amount of 25 per cent of the active pay of their respective grades as provided by the pay tables of the United States Army and Navy, besides mileage while under orders, and directing the committee on legislation of the association to confer with the similar committee of the National Guard Association, and to represent the conditions as they relate to medical officers with a view of obtaining an increased rate of pay for them

Ethics, Scope and Prerogatives of Army Medical Officer

Col L Mervin Maus, M C , U S Army, discussed this subject, which is of interest alike to medical officers of the regular establishment and to those of the organized militia He outlined the advantages to be derived from the blending of the medical corps of the Army with the U S Public Health and Marine Hospital Service, which would bring under one executive, public health, general and special sanitation, quarantine, hospital organization and management, the care of the sick, property responsibility, examinations etc He considers early military training of paramount importance to the medical officer, who should at least have a thorough knowledge of the principles of discipline, military drill and the essentials of command The medical officer of to day must be a man of collegiate education or its equivalent, an accomplished physician, a skilful surgeon, an expert in diseases of the eye, ear, nose and throat, a master of obstetrics, gynecology and pediatrics, an alienist, a past master in military hygiene and sanitation, and a thorough student of military regulations and customs, and army life He must also be proficient in military law, to a certain degree in tactics, especially those relating to hospital corps and ambulance drills, he must understand the art of the architect and builder, the duties of judge advocate, quartermaster, commissary, paymaster, the command of hospitals, hospital ships and trains, ambulance companies and the multitudinous and varied duties connected with municipal administration in all of its complex branches Among the important duties delegated to the medical officer is that of sanitation, whereby the medical officer becomes the army sanitarian in name, if not altogether in function He is authorized to supervise the sanitation of the command to which he is attached and to recommend to the commanding officer such measures as he deems best for the health of all concerned Colonel Maus suggests the greater use of the special sanitary report, instead of waiting and allowing the continuance of an insanitary evil until the monthly report is made He urges that the recruitment of the army be placed in the hands of the medical corps, as the physical examination is the chief factor of the duties of the recruiting officer He also believes that retiring boards should consist entirely of medical officers, who, by reason of education and training, are the only officers in the service competent to pass an opinion as to the physical condition of officers brought before such boards The essayist does not approve of the term surgeon as a designation, preferring the more correct title of medical officer He suggests that the following designations be made official For an army in the field or a military tactical division or department, surgeon general, for a division, division surgeon general, for a brigade, brigade surgeon general, for a general hospital, field and in a proper selection of cases is free from danger, and for many patients much more pleasant. There have been over 1,000 cases already treated by the intravenous method. As an intravenous injection, Alt injects at least 0.3 to 0.4 or 0.5 gm., some give still larger doses, 0.7 to 0.8 gm. The intravenous injection can be repeated after two or three weeks, according to the need of the case, if the curative effect of the first injection is not complete and the Wassermann reaction is still positive. So far, indications of a hypersusceptibility have not appeared, although in many instances intravenous injections have been employed two, three, four or five times. Ehrlich says that the reports that have reached him indicate that the intravenous method deserves prominence over the other methods, especially the subcutaneous. He does not overlook the fact that this method will meet certain technical difficulties in ordinary practice, still it is important in the interest of patients to secure at once the most effective treatment. The *intravenous method is therefore recommended by Ehrlich, at least for hospitals and clinics.* The things to be especially considered are the following: 1. The disease should be put under treatment as promptly and early as possible, as it generally *occurs in robust young individuals.* They should be treated with at least 0.5 intravenously. In addition, it would be advisable, in the interest of actual sterilization, to employ an energetic local treatment, extirpation, cauterization or some of the other methods used. 2. In diseases of the central nervous system and the circulatory apparatus, so far as these are really suited to treatment, the greatest caution is advised and small doses, 0.2 to 0.4, should be used, but whether in these cases the intravenous method does not deserve the preference over the forms of application heretofore used, has not yet been sufficiently determined. Ehrlich, therefore, advises *that in the future*, as far as possible, the intravenous injection should be used.

The Legal Value of Vital Statistics

Mr. W. J. V. Deacon, statistician of the Kansas State Board of Health, in the *Journal of the Kansas Medical Society*, November, 1910, discusses vital statistics, with special reference to their legal and social value. As most discussions of this question relate to the medical and sanitary side of registration, this paper is especially deserving of attention by physicians. While too much cannot be said on the value of properly recorded and tabulated vital statistics as a means of 'sanitary bookkeeping" and as a stimulus to hygienic reforms, it must be remembered that the recording by the state of births, deaths and marriages is of quite as much importance to the lawyer, the business man and the average citizen as it is to the sanitarian. Mr. Deacon lays special emphasis on the necessity of presenting the facts brought out by registration of vital statistics to the attention of the public and keeping these facts constantly in the foreground. He says:

"It has been said that vital statistics can make disease centers as obvious and as offensive as the smoking nuisance. They will not do this, however, unless they are advertised. The compilation of vital statistics as a matter of history is worse than useless and does not begin to furnish an adequate return for the time, money and effort put in their compilation. To be of real value, vital statistics must be a guide to our public health officials, and to every public spirited physician, in the campaign against disease. That the collection and publication of vital statistics is of great importance is a well recognized fact. In international statistics, practically every well-known European state is represented. In addition, I might mention such countries as New South Wales, Tasmania, New Zealand, Ceylon, Jamaica, Finland, Roumania, Bulgaria, Japan and Chili. The United States as a whole, is not represented in international vital statistics."

Mr. Deacon gives three important reasons for recording births and deaths. These are: first, protection of the rights of the individual and of the community; second, the protection of the health and lives of the people; third, the knowledge of the movement of the population. After pointing out that statistical officers are usually under the direction of state or city boards of health and that, for this reason, the legal and social importance of vital statistics has been lost sight of, Mr. Deacon says:

"The interest of lawyers in this movement is generally because the very nature of their profession causes them to appreciate more quickly the disadvantages and financial hardships that individuals so often suffer, but this, like the interests of the physicians from a sanitary standpoint is not based alone on the professional interest of individual practitioners, though it is true that an orderly and authentic system of recording births and deaths would greatly facilitate legal procedure. The greatest benefit will result to the people themselves and not to any one profession."

Mr. Deacon gives seven provisions which should govern the registration of deaths:

1. Deaths must be registered immediately after their occurrence.
2. Certificates of death must be recorded.
3. Burial or removal permits are essential to the enforcement of the law.
4. Efficient local registrars are necessary.
5. The central registration office should have full control of the machinery and its rules should have the effect of law.
6. The transmission and preservation of returns should be provided for.
7. Penalties should be provided and enforced.

Mr. Deacon considers that one of the fundamental purposes of the proposed national department of health is the collection, compilation and use of vital statistics and repeats the three economic reasons given by Allen for the establishment of such a department. These are: first, to enable society to increase the percentage of exceptional men of each degree, many of whom are now lost through preventable accidents, and also *to increase the total population*; second, to lessen the cost of sickness; third, to decrease the amount spent on criminality that could be traced (if there were properly filed and reliable figures from which to draw conclusions) to overcrowded, unwholesome and unhygienic environment.

In discussing the influence of vital statistics on social problems, he says:

"Whenever the term 'statistics' is applied to social facts it suggests action, social control of future contingencies, mastery of the facts whose actions are chronicled. The object of gathering social facts for tabulation is not to gather material for future historians; they are to be used in shaping future history. They are facts collected with a view to improving social vitality, to raising the standard of life and to eliminating permanently those forces known to be destructive to life. Unless they are used in this way they are of interest only to the historian. No city or state can afford to erect a statistical office to serve as a curiosity shop."

This portion of the paper concludes with an arraignment of Kansas which ought alone to be sufficient to secure the enactment of a proper registration law in that state at the next meeting of the legislature:

"Kansas, poor old Kansas! Bleeding Kansas! Bleeding money, wheat and corn at every pore. 'Tis said. A land of smiling sunshine, of winding streams, where you have but to tickle the soil to make it laugh a harvest. A land dotted with school houses and growing towns and villages, called cities by divine right of prophecy. A land of pigs given to adipose, of sleek cattle, of strong horses, of handsome women, of bouncing babies, of homely, rugged men. A land where no one dies except through accident or over eating. Poor, bleeding Kansas cannot afford to pay 25 cents to register those bouncing babies and, while for years they have duly registered their fine pigs, their cows and their horses at an expense of from 50 cents to $10.00 each, they deny to the future citizen, the potential fathers and mothers of this great republic, the right of registration, the establishment of their legal birthright, for the pitiful sum of 25 cents.

"'Have you a little fairy in your home?' If you have she is not registered. No human eye can pierce the future and while you by study, industry and thrift may think to leave that 'fairy' far above the reach of the breakers of misfortune, who knows what may arise in the future to require that little one to prove herself your child, your heir and the right to exercise those sovereign rights of citizenship to which estate the little one has been born, and in which rights you to-day think her secure.

"The state owes to every citizen the right that the three principal events in the life of each of them shall be a matter of public record, and these three events are the birth, marriage and death. This state owes it to you to maintain these records, a duty it has shamefully neglected."

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fifth Month—Second Weekly Meeting

I. HYPEREMIAS OF THE SKIN

ERYTHEMA HYPEREMICUM: Erythema caloricum, e. solare, e. venenatum, e. ab igne, e. traumaticum. Symptoms and treatment.

ERYTHEMA INTERTRIGO: Chafing.

II. INFLAMMATIONS

ERYTHEMA MULTIFORME: Etiology. Symptoms: Constitutional symptoms, visceral manifestations, varied lesions.

ERYTHEMA NODOSUM: Etiology, symptoms.

ERYTHEMA SCARLATINOIDES: Symptoms and diagnosis.

PELLAGRA: Etiology. Symptoms: Disturbances of gastro-intestinal and cerebrospinal systems. Cutaneous lesions—three stages—congestion, thickening and pigmentation, atrophic thinning.

URTICARIA: Etiology. Symptoms. Varied lesions: Urticaria papulosa, u. gigans, u. bullosa, u. hemorrhagica, u. perstans, u. factitia. Treatment.

ANGIONEUROTIC EDEMA: Symptoms. Diagnosis. Treatment.

ECZEMA: Acute, subacute and chronic.
  Eczema erythematosum, lesions, usual locations.
  Eczema papulosum, lesions, locations, course.
  Eczema vesiculosum, lesions, locations, course.
  Eczema pustulosum, lesions, locations.
  Eczema rubrum and e. squamosum; secondary conditions.

REGIONAL ECZEMA.

DIAGNOSIS: Redness; papule, vesicle, or pustule; discharge; crusts and scales; thickening and infiltration; itching and burning. Differentiate from scabies, herpes, dermatitis, impetigo contagiosa, sycosis, psoriasis, lichen planus.

Society Proceedings

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Nineteenth Annual Meeting, held at Richmond, Va., Oct. 31–Nov. 4, 1910

The President, COL. JOSEPH K. WEAVER, N.G., Pa., Norristown, in the Chair

Officers Elected

The list of officers-elect was published in THE JOURNAL, November 5, page 1656. Milwaukee was selected as the place of meeting for 1911.

Reports of Officers

MAJOR HERBERT A. ARNOLD, N.G., Pa., treasurer, reported the largest number of paid-up members in the history of the organization—1,445—and that the balance in his hands was $5,826.41, or $429.09 more than for the previous year.

MAJOR CHARLES LYNCH, M.C., U. S. Army, secretary and *editor, explained that the loss in advertising receipts was due* to the acceptance of no advertisements except those approved by the Council on Pharmacy and Chemistry of the American Medical Association.

Department of Public Health

At the business meeting resolutions were adopted favoring the passage of Senate Bill 6049, now pending, or essentially similar legislation having for its object the establishment of a national department of health, of equal dignity and power with other departments of the government, having at its head a secretary of public health, a cabinet officer.

Pay for Organized Militia

On motion of COL. L. MERVIN MAUS, M.C., U. S. Army, a resolution was adopted asking Congress to provide that medical officers and members of the hospital corps of the organized militia receive an annual pay to the amount of 25 per cent. of the active pay of their respective grades as provided by the pay tables of the United States Army and Navy, besides mileage while under orders, and directing the committee on *legislation of the association to confer with the similar committee* of the National Guard Association, and to represent the conditions as they relate to medical officers with a view of obtaining an increased rate of pay for them.

Ethics, Scope and Prerogatives of Army Medical Officer

COL. L. MERVIN MAUS, M.C., U. S. Army, discussed this subject, which is of interest alike to medical officers of the regular establishment and to those of the organized militia. He outlined the advantages to be derived from the blending of the medical corps of the Army with the U. S. Public Health and Marine-Hospital Service, which would bring under one executive, public health, general and special sanitation, quarantine, hospital organization and management, the care of the sick, property responsibility, examinations, etc. He considers early military training of paramount importance to the medical officer, who should at least have a thorough knowledge of the principles of discipline, military drill and the essentials of command. The medical officer of to-day must be a man of collegiate education or its equivalent, an accomplished physician, a skilful surgeon, an expert in diseases of the eye, ear, nose and throat, a master of obstetrics, gynecology and pediatrics, an alienist, a past master in military hygiene and sanitation, and a thorough student of military regulations and customs, and army life. He must also be proficient in military law, to a certain degree in tactics, especially those relating to hospital corps and ambulance drills; he must understand the art of the architect and builder, the duties of judge advocate, quartermaster, commissary, paymaster, the command of hospitals, hospital ships and trains, ambulance companies and the multitudinous and varied duties connected with municipal administration in all of its complex branches. Among the important duties delegated to the medical officer is that of sanitation, whereby the medical officer becomes the army sanitarian in name, if not altogether in function. He is authorized to supervise the sanitation of the command to which he is attached and to recommend to the commanding officer such measures as he deems best for the health of all concerned. Colonel Maus suggests the greater use of the special sanitary report, instead of waiting and allowing the continuance of an insanitary evil until the monthly report is made. He urges that the recruitment of the army be placed in the hands of the medical corps, as the physical examination is the chief factor of the duties of the recruiting officer. He also believes that retiring boards should consist entirely of medical officers, who, by reason of education and training, are the only officers in the service competent to pass an opinion as to the physical condition of officers brought before such boards. The essayist does not approve of the term surgeon as a designation, preferring the more correct title of medical officer. He suggests that the following designations be made official: For an army in the field or a military tactical division or department, surgeon-general; for a division, division surgeon-general; for a brigade, brigade surgeon-general; for a general hospital, field hospital, hospital ship, hospital train, post hospital or ambulance company, commanding officer; for a medical supply depôt, officer in charge; for a regiment or separate battalion, chief medical officer; and for other officers assigned as juniors, medical officer. Officers assigned to medico-military inspection or sanitary work should be designated medical inspector-general or sanitary inspector-general.

Vaccine Therapy

Major Harlan Shoemaker, M.C. N. G., Pa., Philadelphia, detailed his experience with natural as compared with artificial vaccine therapy, from which he concluded that bacterial vaccines can be undertaken without fear of unpleasant sequelae because the reaction is of short duration, and consequently there is no danger of injury to a vital organ; because the reaction is not so great as in a natural vaccination or inoculation of living germs; because the surgeon inoculates many patients with innumerable living germs without unfavorable results, and because the bacterial vaccine is dead.

(To be continued)

CHICAGO MEDICAL SOCIETY

Regular Meeting, held Nov. 9, 1910

The President, Dr. Alexander Hugh Ferguson, in the Chair

The Ligation or Partial Extirpation of Exophthalmic Goiter

Dr. Charles H. Mayo, Rochester, Minn: There are two groups of cases of hyperthyroidism: first, the simple goiter without symptoms of hyperthyroidism; and, second, the group of cases in which the symptoms of hyperthyroidism constitute the main feature of the case. In cancer of the thyroid it is not uncommon to see marked hyperthyroidism—in fact, some cases have every symptom ordinarily classed as Graves' disease. As to treatment, from an operative standpoint, we will consider the operation of vessel ligation and one of partial extirpation of the gland. For the mild cases, or those seen early, is recommended the simple ligation of the vessels, nerves, and lymphatics at the upper pole, with a linen ligature. Following this procedure the reduction in the delivery and production of secretion seems to bring about that form of reversion of goiter toward the simple type, as demonstrated by MacCarty. The same treatment is indicated in the most advanced cases in which changes in the heart, liver, etc., have advanced to a most serious degree. In this group the improvement is very marked in all who recover from the operation, and the removal secondarily of the larger lobe and isthmus can be made with a marked degree of safety a few months later. Of the cases operated on by ligation who are below weight there is an average gain of 20 pounds in four months. The results from operations are about 70 per cent. cured, and the remainder greatly improved, although operated on at a time when serious and incurable conditions of other organs were present. The mortality for ligation of vessels is 3.7 per cent. The mortality in extirpation cases is 3.9 per cent. This includes the highest mortality of early work. During the past three years twelve patients have died without operation within the first eight days after their arrival in the city for operation, their morbid condition being too evident for surgical treatment at that time.

DISCUSSION

Dr. Arthur Dean Bevan: I believe that the theory of Möbius has been definitely proved to be true, that exophthalmic goiter and the symptoms resulting from this disease are due to the oversecretion of the gland, or possibly, at times, to an altered secretion, and I think Kocher has shown, basing his work on the theory of Möbius, that in order to cure exophthalmic goiter, it is our duty to diminish to approximately normal the internal secretion of the gland. How is this to be done, and at what time are we to resort to operative interference? I have had the same experience that Dr. Mayo has had in losing patints after trying to do too much. I remember three very sick patients I lost in whom I removed one entire lobe and part of another, and I am rather inclined to believe if I had adopted the plan of Kocher, I would have succeeded in some case in saving the patients' lives. I believe in the very bad cases we should ligate one or two thyroid arteries. As to the technic, Crile adopts a rather stealthy way, without any knowledge of the patient beforehand. Some morning he comes into the room and ligates one of the superior thyroid arteries. I have not much sympathy with Crile's method of doing these operations without the full knowledge of the patient. After listening to Dr. Crile's persuasive argument one day I tried it on an intelligent woman, and she never forgave me. I believe that in almost all cases ether is to be preferred as the anesthetic. In some very bad cases cocain may be used in the following way: about an hour before the operation give hypodermically ¼ grain morphin and 1/150 scopolamin; then 1/1,000 solution of cocain should be employed with a little epinephrin added to it.

The technic which I have adopted has been to make a little incision about an inch and a half in length parallel with the normal skin folds in the neck just at the upper border of the thyroid gland, just in front of the sternocleidomastoid. The incision is taken down to the deep fascia; then the sternocleidomastoid is drawn to the side; then the omohyoid passes right in front of the artery. There is this little piece of surgical anatomy which you should remember, and that is, the artery below the hyoid bone is internal to the carotid and the sternocleidomastoid. You find the large artery before seeing the pole of the gland itself. Then you follow that down to the pole. In many of the cases the mere ligation of the superior thyroid will suffice. In the more radical operation of the removal of one lobe of the gland the procedure should be the Kocher incision, and ether anesthesia, as a rule. I think we owe a great deal to Dr. Mayo for showing us that ether anesthesia is quite as safe in the hands of an expert, as I firmly believe it is, as cocain, in the resection of the goiter. The incision should divide the skin, superficial fascia and platysma, and should be very well dissected up, so that a large flap may be made and held by the assistant with a retractor. Then the superficial layer of the deep cervical fascia should be divided in the middle line, and the sterno-hyoid and sterno-thyroid muscles should be drawn to one side. I always ligate the superior thyroid en masse, and then the inferior thyroid. I do not believe we should ever remove more than a single lobe, and if there is a large amount of thyroid left on the opposite side I believe we should complete the operation by the ligation of the superior thyroid on that side. We owe a great deal to Möbius, Kocher and Mayo for teaching us the pathology and treatment of exophthalmic goiter. I believe the time has come when we can say to the patients who have come to us, especially if they come early, "You have exophthalmic goiter; you can be cured by surgical operation with much less danger than by leaving the condition to Nature."

Dr. J. Halpenny, Winnipeg, Manitoba: After a slight amount of experience in experimental work with the parathyroid glands, one is compelled to conclude that at the present time they are not in the practical arena of surgery at all. There are various assumptions regarding those glands that are not fully borne out by experimental work. The statement has been made by many that if the parathyroid glands are all removed, in every case death follows from acute tetany. One is unable to find that this always occurs. One is told that if the parathyroid glands alone be removed death follows more quickly than if the thyroid be also removed with the parathyroid glands. This is not true. Death comes on more quickly with the complete operation than when the surgeon removes the parathyroid glands alone. One finds that when the thyroids are removed and the parathyroids are left behind, there is a certain change in the histologic structure of the parathyroid, so that it takes on the structure of the thyroid. In one animal the lobes of the parathyroids and in another animal the lobes of the thyroids in the two instances appear very similar. This would lead one to conclude that these glands are so closely related that the one is able to take up the work of the other to a certain extent.

In the literature one finds that the argument is put forward that the parathyroid glands are there to check up the thyroid glands; that they are not entirely a different structure, except that they are to check up the thyroid glands, and the statement is made that the probable explanation is this: the thyroid gland normally accumulates or secretes some toxic substance which the parathyroid glands destroy. Remove the parathyroid glands and the toxic substance accumulates very rapidly, and death follows by tetany. The fact that the resultant tissue very closely approximates the tissue when the thyroid is left behind makes it appear that these two glands have work of the same kind to do.

Dr. D. W. Graham: I wish to emphasize the use of a general anesthetic instead of local anesthesia in operating for goiter, especially for the exophthalmic type.

Dr. L. Schooler, Des Moines, Iowa: I was very glad to hear the essayist emphasize one point, and I think it will inure to the benefit of a large number of patients, and that is that all cases of goiter are not surgical cases. I have seen operation in a good many cases of goiter that in my judgment were not surgical cases. Life-saving operations in advanced cases of goiter are bad surgery. Operating when the patient is moribund will not help the statistics in this class of cases any more than it will in any other.

Dr. Alexander Hugh Ferguson: I wish to ask Dr. Mayo to say something with reference to the class of cases in which thyroidism comes on every month or two or three months, and all the symptoms are directed toward the heart, and there is vomiting, with very little enlargement of the gland. There is no protrusion of the eyeballs, no tachycardia between times, no trembling of muscles, and no eye symptoms. I have had two or three such cases. One patient was supposed to die in an extreme condition of depression; he vomited, had diarrhea and became pulseless, but is slowly getting better. This patient was completely relieved by operation.

Dr. C. H. Mayo: If you deem it better to do a thyroidectomy to begin with, and a relapse takes place, with a little enlargement of the left lobe, then it is advisable to ligate the artery and lymphatics on that side, leaving one artery and three veins to supply the gland. If we have not cured the disease, it does not mean that we are through with the patient. If a relapse takes place, the patient can be made better by resection or ligation first, and following after that, after taking out the right lobe, and afterward ligating the superior vessels on the left side, I have resected a part of the left lobe in four cases, using a mattress suture. We have many more cases of exophthalmic goiter in this country than they have in Europe. The operations in this country that have produced tetany have been mostly secondary operations on the remaining lobe. No cancer patient has been cured if there was involvement of the lymphatic glands of the neck. The exophthalmic cases can be improved once or twice with the x-ray, and then comes the operation.

AMERICAN ASSOCIATION FOR THE STUDY AND PREVENTION OF INFANT MORTALITY

(Continued from page 2090)

First Annual Meeting, held at Baltimore, Nov. 9-11, 1910

Philanthropic Prevention of Infant Mortality

Dr. H. H. Hart, New York City: A study made by the Russell Sage Foundation, at the request of Mr. Homer Folks, revealed the fact that accurate information with reference to the mortality of infants under the care of philanthropic institutions is greatly needed as a basis for preventive effort. Very little accurate information exists, and that which is obtainable does not exist in such form as to permit intelligent comparison. Thirty institutions, including infant asylums and other institutions which care for infants under 2 years of age, were visited. Statistics were obtained partly from published reports and partly from figures furnished by the superintendents of institutions. Reports received from twenty-two institutions showed that out of 56,451 children under 2 years of age received by the institutions, 22,743 died, a mortality of 40.3 per cent. In many instances the rate was higher, varying from 50 to 70 per cent. In one instance the head of an infant asylum reported that during the past twenty years the death-rate among children under 2 years was 75 per cent. The statistical reports of boards of health and of state boards of charity afford no usable material. Institutional statistics were found to be misleading, because of the practice of treating each year as a unit, and basing the death-rate on the entire number of children cared for during the year. For instance, one institution which had fifty infants on hand at the beginning of the year received 100 and had fifty deaths, an apparent death-rate of 33⅓ per cent. If, however, the statistics were considered for a series of years, the rate would be found to be nearer 50 per cent. An intelligent study of infant mortality should deal with infants under 1 year. The inquiry referred to revealed the fact that not only was there a lack of uniformity of recording the personal and medical history of infants under care, but that no system that could be considered fairly complete had been perfected for recording such histories. The individual study of each case is required.

The following conclusions have been reached as a result of the study up to the present: First, there is room for improvement in the care of infants even by the most conscientious societies; second, there is a surprising amount of ignorance of their wards by societies. Only a few have an accurate history of their wards, and only a very few have proper medical examination on admission; third, nurses and superintendents of infant asylums are eager for information which will enable them to give adequate care to the infants placed in their charge.

DISCUSSION

Dr. W. C. Woodward, Washington, D. C.: Is there a record of mortality in the asylums?

Dr. S. Josephine Baker, New York: I have prepared a chart showing deaths in different localities in New York City, which brings out the fact that almost half of the infant mortality in the Borough of Manhattan is the institutional mortality. The real problem of the institution is not the breast-fed baby, but the bottle-fed baby. The boarding-out method of caring for babies should be elaborated more for the bottle-fed than the breast-fed baby. The bottle-fed baby boarded out in a home has a chance for life; 50 per cent. greater than if kept in an institution.

Dr. W. C. Woodward: Does any one know of a community in which an official or public register is kept of available wet nurses? The suggestion has been made to me by Dr. Skinner of the Columbia Hospital in Washington, that the frequency of applications for wet nurses by people of means makes it desirable that such a register be kept.

Mr. Walter Kruesi, Boston: The Boston Floating Hospital instituted a system of collecting maternal milk last summer from mothers who could spare it. The hospital offered 50 cents a quart, but the mothers refused to accept pay, preferring to contribute it for any child who needed it.

Mr. Robert W. Bruere, New York City: The question of wages enters largely into the care of infants. Ten per cent. of the mothers in the New York Lying-In Hospital come from families in which the weekly income is $5 or less. A study of the records of 6,000 confinements in 1909 showed that 1,700 were without employment when the child came; in 10 per cent. the income was $5 or less; only about 5 per cent. had an income of $15; and one-fifth of the families represented in the study had children of wage-earning age. I question Dr. L. K. Frankel's assertion that maternal insurance is not needed in America because husbands usually support their wives adequately.

Dr. L. K. Frankel: I object to a system of maternity insurance because I object to married women working. The average woman is doing her full duty to the community when she cares for the child she brought into the world. The economic conditions of the country should be readjusted so that the wage-earning power of the husband will be sufficient to enable him to support his family. The system of maternity insurance developed in Germany and Italy takes into account the problem of the illegitimate child.

Dr. Leonard D. Frescoln, Philadelphia: The Philadelphia General Hospital is in touch with various charity societies, and looks out for foundlings reported through these societies. Wet nurses are usually obtained from the obstetric or gynecologic wards of the City Hospital. The women are required to take their babies with them. Pay is usually from $6 to $8 a week.

Mrs. William Lowell Putnam, Boston: In Boston a plan has been followed of sending women out as wet nurses by day only; if for a longer time they take their own babies with them. The arrangement has made it possible to secure the services of a self-respecting class of married women.

Dr. C. O. Probst, Columbus, Ohio: There is a necessity for licensing boarding-out hospitals and places in which women go for confinement. Such a law is operative in Ohio. An examination is made of the place before the license is granted; no child born in such an institution can be placed anywhere in the state without the knowledge and consent of the authorities.

The Relation of Infant Welfare to the General Social Movement

Mr. Sherman C. Kingsley, Chicago: The relation of infant welfare work to the general social movement is about the same as that of the baby to the adult population. The baby makes the population, and out of neglected babyhood come the individuals that furnish the task of charity workers, of reform agencies and those engaged in the general social movement. Infant mortality and poverty go hand in hand. The black dots on the map of any city marking the location of baby funerals will also lead to the homes of the poor. The worker who becomes acquainted with these families discovers the mother who must go out to work to earn a living for herself and children, who has been deserted by her husband, who lives in insanitary tenements, who lives in a part of the city where the problem of poor milk is at its worst, where the alleys are foulest and flies are thickest. There is no problem affecting the home which does not rest finally with the greatest severity on the baby, and the worst effects often even before it is born. The problem of social disease and race responsibility is perhaps never appreciated so fully as when one sees its effects and reads its lesson in the baby victim. Every activity in behalf of human life receives new significance and meaning when the problem of the family and the home is approached with reference to its fitness as a place to welcome and foster infant life.

DISCUSSION

Miss C. Van Blarcom, New York: One point not touched on in the paper is the relation of the midwife problem to the production of blindness among infants. About 50 per cent. of the births in Chicago are attended by midwives; 75 per cent. in St. Louis. Midwives in America are not trained women; with a few exceptions they are not well supervised. It is as important that the midwife be trained as the doctor or the nurse. Consequences of lack of training are shown in diseases which follow the trail of the midwife. European midwives are carefully trained.

Mr. Edwin D. Solenberger, Philadelphia: Apropos of the relation of infant welfare work to the social movement, it is important that a definite plan of action be formulated for each community, with a certain part in it for each activity engaged in the campaign against infant mortality. A particular effort should be made under the department of health at the beginning of the hot weather to correlate and strengthen the agencies enlisted in the welfare campaign.

Dr. S. W. Newmayer, Philadelphia: The plan referred to by Mr. Solenberger is carried out in Philadelphia. All the various organizations engaged in infant welfare work are organized into one central bureau which forms a clearing-house for the work. It would be difficult to enforce laws prohibiting the employment of women before confinement. It might be practicable to have the women visited by visiting nurses, the expense of this care and instruction to be borne by small subscriptions from the various factories.

Mr. Louis Levin, Baltimore: A Jewish association in Baltimore which cares for women during their confinement sends trained care-takers into the homes while the mothers are incapacitated. Realizing the necessity for training the care-takers, arrangements were made in accordance with which the Hebrew Hospital agreed to open a training class for these workers. Instruction is simple, but enables care-takers to give intelligent attention to the needs of mother and child. The course is to cover one year. The present force of untrained care-takers receives $6 to $8 a week.

Miss C. Van Blarcom, New York City: The Central Midwives Board, appointed by act of Parliament in 1902, establishes standards for training schools. Examinations are required of pupil midwives trained in these schools. The training is analogous to that given to obstetric nurses in this country; the course includes elementary instruction in hygiene, anatomy and physiology.

Infants' Milk Depots and Infant Mortality

Mr. Wilbur C. Phillips, New York City: The milk depot is the fulcrum on which rests the lever of the situation—the instrument through which medical, social, educational and philanthropic prevention effect their purpose and achieve success. Operated as it should be, it is more than a depot from which milk is distributed. It is an educational center, a district branch for the dispensation of relief, and an indispensable coordinating unit between nurses, physicians, clinics, dispensaries, hospitals and various philanthropic institutions which concern themselves directly with the welfare of the child. We should have classes for mothers in infant hygiene; periodical consultations under the direction of physicians for weighing and examining the babies, and follow-up work in the home by visiting nurses. If infant mortality is to be prevented and not cured, the home must be the crucial place of attack. The work of infants' milk depots must be coordinate with the hospitals, clinics, dispensaries, floating hospitals, fresh-air homes, day nurseries and all the agencies which are interested in the baby problem. Before birth the depot nurse, through her intimate knowledge of these agencies, will assume the responsibility of preparing mothers for a successful delivery. After the baby is born she will continue to look after it and will place at the mother's disposal every known means of bringing it to strong and healthy childhood. The milk depot is the natural coordinating unit in all this work because of its proximity to the home. In the last analysis, infant mortality is to be solved, not by philanthropy or by institutions, or by the medical profession, or by the state, but by intelligent motherhood.

The assistance and supervision exercised over mothers from the period before confinement until the child is weaned should be as uniform as possible with respect to instruction given and methods taught. Probably some day the instructional work to prevent infant mortality, which at present is being paid for either by philanthropy or given gratuitously by physicians, will be taken over by our cities or towns. Already in New York City we have seen organized the Bureau of Child Hygiene, with the great corps of nurses working at least during the summer among the babies, and it is not unreasonable to expect this work in New York City and elsewhere to continue permanently throughout the year.

DISCUSSION

Dr. L. T. Royster, Norfolk, Va.: The educational features of the infants' milk depots represent the most important aspects of the work. We should teach mothers to modify the milk in their own homes. I favor the teaching of the essentials of infant hygiene and infant feeding in the elementary grades of the public schools.

Dr. S. Josephine Baker, New York: The Little Mothers' Leagues in New York City are voluntary organizations formed among the girls of 12 or over in the public schools in sections of the city where the older children have much of the care of their younger brothers and sisters. Meetings are held weekly, the doctor and nurse of the school serving as honorary president and vice-president. Children are given practical instruction in the preparation of food for infants; they are taught to modify milk, to bathe the baby, and other simple fundamental rules of infant hygiene and home sanitation. Over 22,000 members are enrolled in the league.

Dr. Ira Wile, New York: Two points should be emphasized in a consideration of milk depots. First, the possibilities of caring for the breast-fed baby for whom mixed feeding has to be resorted to when the mother is employed during the day. The breast-fed baby is more welcome than the one entirely artificially fed. Second, milk stations are for well children, not sick ones; they offer means of keeping babies well, not of curing them when they are ill. The third function of the milk station is to teach the ante-natal care of the breasts. Instruction should also be given in personal and household hygiene, and in dietetics. Classes for mothers are a potent means of reducing infant mortality.

Dr. J. H. Mason Knox, Jr., Baltimore: The Maryland Association for Study and Prevention of Infant Mortality is a mother's relief society and milk depot combined. The association employs a physician to conduct classes for mothers, an obstetrician, a staff of trained nurses, and a social worker. The society is doing much toward combating the evils of the midwife problem.

Miss Lydia Holman, North Carolina: I am a visiting nurse in the mountains of North Carolina. The baby in the isolated communities has no chance, and my work was begun in order to secure more of a chance for mothers and babies in the mountainous districts. During eight years I have delivered 308 women. I hope that the plan for the extension of visiting nursing, with the possibilities it offers in the teaching of hygiene and home sanitation, will eventually reach every rural community in the United States.

(To be continued)

PHILADELPHIA COUNTY MEDICAL SOCIETY

Regular Meeting, held Nov. 9, 1910

The President, Dr. Henry Leffmann, in the Chair

TO WHAT EXTENT, IF AT ALL, SHALL THE PRACTITIONER REGARD INTESTINAL ANTISEPSIS AS FEASIBLE?

The Scientific Evidence of the Possibility of Influencing Bacterial Growth in the Intestines

Dr. Horatio C. Wood, Jr.: There is no disinfectant strong enough, in doses which would be safe, to destroy the viability of the bacteria in a quantity of fluid equal to that of the bowel. For such an effect it would require about an ounce of phenol or 5 grains of corrosive sublimate. On the other hand, it is theoretically possible to exercise an antiseptic influence, that is, to restrain the development of bacteria. For this purpose, in a quantity of culture medium equal to the contents of the intestine, it would require: phenol, 3 drams; creosote, 30 minims; solution of formaldehyd, 13 minims; betanaphthol, about 9 grains. These figures do not take into consideration the possibility of the absorption. A critical examination of the experimental data as to the effect of chemical agents on the intestinal flora confirms this conclusion, and shows that it is at least within the bounds of hope to reduce the number of bacteria in the bowel with antiseptic agents. Present evidence shows that the official drug from which the most is to be expected is probably betanaphthol as it is the one in which the margin between safe dose and antiseptic power is the largest, with the exception of formaldehyd, and also that it is slowly absorbed and therefore likely to remain in the bowel long enough to do good.

Intestinal Antisepsis

Dr. Albert E. Roussel: The beginning of intestinal antisepsis may be traced back to 1872 when Selmi discovered in the products of putrefaction certain substances resembling alkaloids which he called ptomains. The phenomenon that the products of bacterial life are lessened after the administration of intestinal antiseptics indicates that their antiseptic effect is a matter of fact rather than of conjecture, since bacterial cultures do not tend to spontaneous cessation of growth even in so fertile a field as the intestinal tract. Either the intestinal antiseptics act by their own germicidal effect, or they stimulate the formation of organic substances that have the same effect. The contents of the intestinal tract have little effect in neutralizing the chemical antiseptics. A point of particular importance is not to confuse the medical conception of antisepsis with the surgical one of asepsis. Of my typhoid fever cases in the Howard Hospital by far the greater number have been treated with intestinal antiseptics. The mortality has been 4⅓ per cent.

Intestinal Antiseptics in Childhood

Dr. Alfred Hand, Jr.: Strictly speaking, our aim should be not to retard the growth of microorganisms in the intestinal tract but to kill those germs that are causing trouble. In a consideration of the intestinal flora it is well to note the captions given by Moro that in health the intestinal flora depend on the kind of food taken by the infant, a diet rich in starch favoring the development of the fermenting saccharolytes, while food rich in albumin favors the growth of the putrefying proteolytes, and as Escherich pointed out, the possibility therefore exists of restraining intestinal putrefaction by giving starch plentifully; for fermentation and putrefaction cannot go on in the same medium. We must consider the patient first of all and do him no harm while ridding the intestine of the hostile germs. We should strive for the prevention of enteritis by avoiding the introduction of the disease producing germs. Clean milk is a necessity, and it is safer for at least nine months of the year in this climate to pasteurize the milk taken by infants and children. If the disease has gained a foothold, milk and all milk foods must be absolutely forbidden until the discharges have lost all evidences of inflammatory processes, and all remains of milk in the alimentary canal must be removed by purgation or colonic irrigation. The patient is now in the stage when the use of intestinal antiseptics may be considered. I regard thymol, the naphthol derivatives and phenyl salicylate, or salol, as too irritating. A comparison of two series of cases, one treated solely by the starvation plan, and one with bismuth salicylate, showed net results decidedly in favor of the drug. The drug seemed to have undoubted disinfectant properties which Steele's careful investigation proved mathematically. I would sound a word of warning in the use of calomel in these cases. The more I see of its use the more disinclined I am to employ it. To have any value, the bichlorid, into which it is converted, must be present in such amount as would seem to be irritant if not positively toxic.

Intestinal Antiseptics in Pregnant Women

Dr. Edward P. Davis: Advanced pregnancy renders inevitable intestinal stasis from pressure. The result of this stasis is an effort on the part of Nature to protect the woman, and perforation may threaten. Constipation of pregnancy demands attention, and the pregnant woman must be considered as inevitably constipated. Our effort must be toward providing a diet which shall be poor in the materials tending to putrefaction. I have seen as much good result from the use of compound licorice powder as from any other remedy. Attention must also be paid to maintaining muscular tonicity. Personally, I should be unwilling to give any drugs in the doses recommended in the treatment of the pregnant woman because of the danger to the kidneys.

DISCUSSION

Dr. J. P. Crozer Griffith: I think it most important that we study the chemistry of foods, withdrawing that food which does the harm. The modification of the food is the important element both before and after the development of disease.

Dr. James W. Walk: My own feeling in regard to intestinal antisepsis is that we are not sure that any dose which is safe to use does a great deal of good, although there may be a possibility. Of great importance is the washing out of the intestine in a rational way. Generally the free use of water by the mouth is of advantage.

Dr. Henry Leffmann: In this connection the symbiotic relation of bacteria may well be considered. Bacteria in many cases act not singly but by combination.

State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, January 10. Chairman, Dr. W. H. Sanders, Montgomery.

Arizona: Phoenix, January 3 4. Sec., Dr. Ancil Martin

Colorado: Denver, January 3. Sec, Dr S D. Van Meter, 1723 Tremont Place, Denver.

District of Columbia: The District Bldg, Washington, January 10 Sec., Dr. George C Ober, 125 B St., S-E

The following questions were asked:

ANATOMY

1 Describe the most characteristic difference in the male and female skeletons 2 Describe the levator ani muscle 3 Give relations of important structures in axilla. 4 Rectus abdominis muscle—origin, insertion, sheath, description of muscle, actions 5 Locate spleen, celiac axis, astragalus, liver outlines, Scarpa's triangle, incus, Haversian canals, parovarium, urachus, falx cerebri

PATHOLOGY

1 Describe the process of infection [illegible] phagocytosis 2 Describe the process of [illegible] Describe the process of pigmentation, of [illegible] suppurative inflammation, diphtheric inflammation 5 Describe the structure of a sarcoma; name types of sarcomata 6 Give pathologic lesions of lobar pneumonia and of capillary bronchitis 7 Describe the structure of a carcinoma; name the principal varieties of carcinomata. 8 Describe the process of primary healing; of secondary healing 9 Give the pathologic lesions of acute myelitis, of acute spinal meningitis, and acute anterior poliomyelitis 10 Describe the lesions of chronic parenchymatous nephritis and chronic interstitial nephritis

CHEMISTRY AND TOXICOLOGY

1 Mention four official lead preparations and give their chemical formulas 2 Mention two sources of salicylic acid and describe the action and compound formed when combined with bicarbonate of soda 3 Give Latin name, chemical formula and mode of preparation of yellow prussiate of potash (*b*) Give process for making cyanid of potash (*c*) What is red prussiate of potash? 4 Give symbols and atomic weight of (*a*) hydrogen, (*b*) oxygen, (*c*) silver, (*d*) lead 5 Give full official title and chemical formula of tartar emetic 6 What is the source of phosphorus, (*a*) pilocarpin, (*b*) saccharin, (*c*) with antidotes for the first two? 7. How many minims of Megendie's solution are necessary to represent ¼ grain of morphin? 8 What do you understand by corrosive poison? How soon after the poison is taken will symptoms follow? 9. Explain the action of potassium permanganate and tannic acid as an antidote for opium. 10 What is the difference between sulphids, sulphites and sulphates?

PHYSIOLOGY

1 What effect is produced on the heart's action by stimulation of the cardio inhibitory center? By stimulation of the pneumogastric nerve? 2 Describe the glands and villi of the intestines 3 Describe the digestion of a meal of beefsteak and potatoes 4. Describe the process of absorption by the blood vessels and by the lymphatics. 5 What is the effect of an excessive meat diet? 6 Name eight secretions and describe the functions of each 7 Define metabolism, anabolism, catabolism What are the objects of metabolism? 8 What are the functions of the pneumogastric nerve? 9. Describe the seminal fluid Through what structures does it pass? 10. What are the sources of animal heat? How is normal body temperature regulated?

HISTOLOGY

1 Mention methods of cell division, giving examples 2 From what primary layer is the kidney developed? nails? bone? muscle? epithelium of bladder? 3 Mention three varieties of cartilage and give example of each 4 Describe the structure of the uterus 5 Mention five ductless glands.

HYGIENE

1. Admitting that personal infection is the chief means by which diphtheria is carried from place to place, what meteorologic conditions have invariably preceded the most extensive epidemics of that disease? 2. How much linear wall space and how much air space per bed should be available in a ward for contagious diseases? How often should the air be changed? 3. What is meant by the "propulsion" or "plenum" method of ventilation for hospitals, and what are its good and bad points? 4. How high a temperature is required to expel the alcohol from yeast bread? (a) What is the temperature of the baker's oven? (b) Is the loaf effectually sterilized in the baking? 5. What effect has the temperate use of alcoholic spirits on the general health? (a) So used, what is the principal source of elimination? 6. What benefits are derived from the use of tea and coffee and how should these beverages be prepared to obtain healthful results? 7. What are the antiscorbutic properties of potatoes? 8. In changing from extremes of heat to cold, or the reverse, how does the body conserve its forces? 9. What has been the influence of sewage irrigation, or farming, on the general health of those living on the land or engaged in the work? 10. Name the principal methods for the disposal of excreta and sewage.

OBSTETRICS

1. Give the names of the bones which constitute the pelvis and give the diameters at the superior strait. 2. Give the diagnostic signs of pregnancy. 3. Give the etiology, symptomatology and treatment of puerperal eclampsia. 4. Describe the treatment for adherent placenta. 5. Give the diagnosis and treatment for placenta prævia. 6. Give the indications for the induction of abortion. 7. Describe the mechanism of an L. O. A. presentation. 8. Describe the treatment for puerperal infection. 9. Give the diagnostic points of an extrauterine pregnancy. 10. Give the etiology, symptomatology and treatment of mammary abscess.

GYNECOLOGY

1. Give the symptoms, objective and subjective, of uterine anteversion and retroversion. 2. Give definition, pathologic changes, causes and symptoms of senile endometritis. 3. Classify uterine fibroids as to location and differentiate between a submucous and interstitial tumor. 4. Tabulate points of difference between chancre and chancroid on the external genitals of the female. 5. Name the different situations in which hernia of the ovary has been found, and state when palliative treatment is indicated and when radical treatment. 6. Give the indications, action and technic for the intrauterine douche. 7. Tabulate diagnostic points between an inverted uterus and a uterine polypus. 8. Tabulate clinical history (only) of ascites and ovarian cyst. 9. Define subinvolution of the uterus and describe the pathologic changes which are coexistent in the pelvic organs. 10. What are the indications for treatment in case of gonorrheal infection of the endometrium?

DIAGNOSIS

1. Describe the temperature curve and give the diagnostic points in a typical case of typhoid fever. 2. Describe a test for the demonstration of the *Bacillus tuberculosis*. 3. Give the symptoms and physical signs of a right-sided lobar pneumonia. 4. Differentiate between rheumatic fever, pyemia with suppurative arthritis and gonorrheal arthritis. 5. Differentiate between carcinoma of the stomach and gastric ulcer. 6. Give the symptomatology and diagnosis of exophthalmic goiter. 7. Describe the symptoms of rachitis. 8. Describe the urinary findings in diabetes mellitus and chronic interstitial nephritis. 9. Differentiate between the comas of apoplexy, hysteria, alcoholism and uremia. 10. Differentiate between measles and scarlet fever.

PRACTICE OF MEDICINE

1. Give the etiology and symptoms of obstruction of the ductus communis choledochus. 2. Give the etiology and symptoms of diabetes insipidus. 3. Give the etiology and symptoms of peptic ulcer of the stomach. What special symptoms would suggest ulcer of the duodenum? 4. Describe a pancreatic crisis. Give the symptoms of acute pancreatitis. 5. Give the etiology, lesions, symptoms and prognosis of Addison's disease. 6. What is the etiology of cretinism, its lesions, symptoms and prognosis? 7. Give the causes, lesions and symptoms of perinephritic abscess. 8. What are the symptoms of acute anterior poliomyelitis? 9. Give the causes of hematuria. How may the source of the blood be inferred? 10. Describe the symptoms and course of pseudoleukemia.

SURGERY

[illegible] classification, symptoms, pathology, [illegible] conditions caused by disturbances of [illegible] nost dependable in closing openings in abdominal hernias? 4. What is acromegaly? Opsonin? Phagocytosis? Dermoid? Anaphylaxis? 5. Severe crushing injury of foot. Expectant treatment? Indication for amputation? Give technic of any classical amputation of foot. 6. Carcinoma of the breast. Give diagnosis and technic of operation. 7. Give diagnosis and treatment of tuberculous disease of the hip-joint. 8. Give technic of gastro-enterostomy. 9. What is the Fowler position? Bier treatment? Pott's disease? Wassermann reaction? Murphy method of proctoclysis? 10. Differentiate cholelithiasis.

MATERIA MEDICA AND THERAPEUTICS

1. What is an alkaloid? A glucosid? A resin? A gum? 2. What is the active principle of nux vomica? Mandrake? Aloes? Jaborandi? Belladonna? Give dose of each? 3. Senna: Mention the several varieties Where is it found? What part of the plant is used? What are its medicinal properties? 4. What is the alkaloidal strength of gum opium? Of cinchona bark? 5. What is the common name of staphisagria? What are its therapeutic uses? 6. Give the physiologic action of ergot and name the conditions that indicate its use in labor, and the contra-indications? 7. What are the advantages in the use of chloroform as an anesthetic, and what are the signs indicative of danger in the patient? 8. Explain how antitoxin causes immunity and effects a cure, and the methods of administration as a prophylactic and curative agent. 9. What is cumulative action? Name one drug that has this tendency and give symptoms of such action. Explain the constipating action of opium.

Book Notices

INNERE SEKRETION. Ihre physiologischen Grundlagen und ihre Bedeutung für die Pathologie. Von Dr. Artur Biedl, Wien. Mit einem Vorwort von Dr. R. Paltauf, Wien. Cloth. Price, $5.50. Pp. 538. Berlin: Urban and Schwarzenberg; Rebman Co., New York American Agents, 1910.

In this valuable book the author aims to give and gives with complete success, a connected, comprehensive, well-considered and critical presentation of our knowledge of internal secretions.

In a short general part there is traced briefly the development of the ideas of neural and humoral correlation of organs up to the definite establishment by Claude Bernard and Brown-Séquard of the conception of internal secretions. This conception is then defined and its limits drawn, the origin and modes of action of hormones outlined, and the methods and materials used by investigators in developing our knowledge of internal secretions detailed.

In the special part, which constitutes the bulk of the book, the author takes up the thyroid apparatus, the thymus, the adrenal systems, the hypophysis, the pineal gland, the internal secretions of the reproductive organs, of the pancreas, the gastric and the intestinal mucous membranes, and of the kidneys.

In the case of the ductless glands, the development, the human and comparative anatomy, the physiology and physiological chemistry, the pathology, spontaneous as well as experimental, the effects of removal, and the therapeutic relations are fully considered. In each case the development of the knowledge is set forth in an interesting manner. In connection with the adrenals the presentation of the complex embryology and anatomy and of the mode and range of action of adrenalin is furthered materially by means of tabular summaries. The author, himself an active investigator in the fields in question, commands all divisions of the very extensive literature completely. The discussions of moot questions are marked by keen judgment; the difficulties in the way of final opinions are fully stated; and the author carefully avoids further complications by the introduction and advocacy of unnecessary hypotheses. The bibliography, which is not claimed to be complete in any sense, covers 180 pages, and it may be said that it covers the most important literature very well.

There are no illustrations and as the title indicates no attempt is made to discuss from the practical point of view the clinical course, the diagnosis or the treatment of diseases due to disturbances of internal secretions.

Biedl's book will be of great help to students and investigators and is a welcome addition to our literature.

Professor Paltauf writes an interesting preface.

CHILDREN'S DIET IN HOME AND SCHOOL. With Classified Recipes and Menus. A Reference Book for Parents, Nurses, Teachers, Women's Clubs and Physicians. By Louise E. Hogan, Editor of "The Children's Library." Cloth. Price, 75 cents net. Pp. 128. New York: Doubleday, Page & Co., 1910.

This attractive appearing little volume is one of a type that is unfortunately not rare and which, therefore, deserves more comment than it would in itself warrant. The author of this "reference book for parents, nurses, teachers, women's clubs and physicians" is a lay woman who is also editor of "The Children's Library" and author of "Stories for Children," "How to Feed Children," "The Education and Amusement of Children," etc. A number of pages of this book are devoted to infant-feeding and these best illustrate the point here emphasized. This field that the pediatrician of wide experience and profound training goes into with fear and uncertainty, the author enters as calmly as if she were telling a fairy tale to a child. Only a direct quotation can fully convey this ingenuousness. We are told: "Milk prepared with Fairchild's peptogenic milk powder may be used as a substitute without fear during the whole period of early bottle feeding and weaning. An actual study was made by Fairchild of cow's milk and of human milk, and by certain definite stated methods the former was brought to closely resemble human milk. Certainly science need go no further in its search for a suitable food for an infant deprived of its natural supply than to provide a substitute which is recognized as ore resembling nature by those who are supposed to know, hence mothers who wish to follow Nature's laws have here an opportunity to do so A useful little 'red letter' circular of four pages gives in a brief form all the directions necessary in both ordinary and unusual cases"

How simple, and withal how comprehensive! The science and art of infant feeding, normal and abnormal, that has been the storm center of pediatric discussion for decades, reduced to four 'red letter" pages advertising a patented baby food! The strange thing is not that the author believes all this, for she has evidently read certain advertisements very carefully and they read convincingly, but that an intelligent layman should know so little about infant feeding as to undertake to write about it in a book for physicians, or, for that matter, for parents Further comment would be unkind, for the author is evidently earnest and sincere Only a sense of duty has prompted the foregoing comments Such books are distinctly pernicious, because to the uninitiated they bear the stamp of authority.

A Manual of Chemistry Theoretical and Practical Inorganic and Organic Adapted to the Requirements of Students of Medicine By Arthur P Luff M D Physician to St Mary's Hospital and Hugh C H Candy B A Lecturer on Chemistry in the London Hospital Medical College *Cloth Price $1 75 Pp 622, with 46 illustrations* Chicago Chicago Medical *Book Co*, 1910

This is a complete manual of chemistry for medical students in a small, compact and convenient volume The book covers the usual ground gone over in medical colleges and in addition material intended for such students as may expect to take examinations requiring knowledge regarding the testing of compounds This is especially noticeable in Part II, in which the technic for gas analysis is given, which is required in some examinations in England, but which in this country is entirely unnecessary The work also goes further in physical chemistry than usual The book may be considered very complete as a regular text for college students but appears to go into details which are unpractical for medical students

Mentally Deficient Children Their Treatment and Training By G E Shuttleworth B A M D Medical Examiner of Defective Children to the Willesden Education Committee, and formerly to the School Board for London etc and W A Potts, B A, M D Consulting Medical Officer National Association for the Feeble Minded etc Cloth Price $2 net Pp 236 with illustrations Philadelphia P Blakiston's Son & Co, 1910

The book devotes little space to pathology, but enters fully into the clinical features of mental deficiency, beginning with an interesting historical summary of the treatment of defective children The authors lay greatest stress on the treatment, mental, moral, and especially industrial, etiology, classification, and prognosis are treated at length The book can be commended to the physician as a broad, sympathetic and thorough discussion of this important subject

The Refractive and Motor Mechanism of the Eye By William N Souter, M D Associate Ophthalmologist Episcopal Eye, Ear and Throat Hospital, Washington, D C *Cloth Price, $2 Pp 347,* with 148 illustrations Philadelphia The Keystone Publishing Co, 1910

The author gives a commendable exposition of the mechanics and physics of optics and of the refractive and motor mechanism of the eye with reference to the correction of its visual defects by lenses and nerve tract and muscle exercises *Though* elementary in character, the book gives a sufficiently full and clear explanation to aid the student or physician in acquiring a practical knowledge of the subject An appendix contains algebraic formulas to elucidate the various optical problems The book is well illustrated

Treatise on Diseases of the Skin For the Use of Advanced Students and Practitioners By Henry W Stelwagon M D, Professor of Dermatology in the Jefferson Medical College Phila Sixth Edition Cloth Price, $6 net Pp 1195, with 323 illustrations Philadelphia W B Saunders Co, 1910

This work in its various editions has received such wide approval from the profession that it has become one of the standard works on diseases of the skin No further word is needed in regard to it than to say that in this edition it has been revised and many new subjects, new treatments and new illustrations included As reflected in new editions in other branches of medicine, the increased interest in tropical diseases in recent years has brought forth a number of new skin affections, which are described for the first time.

Index Catalogue of the Library of the Surgeon General's Office, United States Army Authors and Subjects Second Series Vol XV S—Skin Grafting Cloth Pp 777. Washington Government Printing Office, 1910

The fifteenth volume of the second series of this index catalogue contains 8,804 author titles, representing 4 688 volumes and 7,460 pamphlets, together with 3,616 subject-titles of separate books and pamphlets and 28,328 titles of articles in periodicals

Admissible Opinion Evidence Where Insanity is the Defense to Crime

The Supreme Court of Oregon holds, in the homicide case of State vs Roselair (109 Pac R 865), where the special defense was insanity, that it was not error to permit a medical expert, who made a personal examination of the defendant two or three days after the homicide, and observed his mental condition, to answer the question, propounded by *the district attorney 'What would you say as to whether* or not he knew right from wrong, and appreciated the consequences of his acts and the nature and quality of his acts?"

The court says that the line of demarcation between sanity and insanity is so indistinct, in some instances, that it is difficult even for a physician to determine them accurately It is also perplexing for a medical expert to explain the extent of mental infirmity, or to elucidate the degree of intellectual strength so that a person unacquainted therewith may gain a correct idea of the capacity or responsibility of a person whose particular act is the subject of judicial inquiry In order, therefore, to adapt the language of a witness to the understanding of men of ordinary intelligence, courts have permitted answers to be given which would seem almost to trench on the issue that the jury were called on to determine It must be admitted that a conflict of judicial utterance exists in respect to this manner of proving a relevant fact But this court believes that the rule adverted to, though founded in necessity is fortified by reason and supported by authority Thus inquiries calling for opinions respecting the capability of a person charged with the commission of a crime, to distinguish between right and wrong have been permitted to be answered by witnesses called for that purpose

The rule is well settled that a medical expert who has made a personal examination of another, for the purpose of determining his capacity to execute a contract, or his responsibility for the commission of a crime, may express an opinion as to the mental condition of such a person at the time of the investigation A qualified physician may also be allowed by a court to assert an opinion from an examination made of a defendant subsequent to the commission of a crime as to whether or not the person accused thereof was sane or insane at the time the offense was perpetrated In cases of derangement, the indications of the infirmity frequently manifest themselves for some time after the paroxysm of dementia, and for this reason evidence of recurring symptoms is admissible after the commission of an act asserted to have been perpetrated while laboring under a state of mental exaltation or depression From such testimony the jury are authorized to deduce an inference as to whether or not the act in question resulted from a mind that was disordered

Contract with City Health Officer for Services in Epidemic Held Invalid

The Supreme Court of Minnesota holds that a demurrer was properly sustained to the complaint in the case of Bjelland vs City of Mankato (127 N W R 397), which was brought by the plaintiff, who was health officer of the city, to recover $1 695 for necessary services rendered in connection with eradicating and controlling an epidemic of small pox and typhoid fever in the city in 1908, pursuant to an alleged contract with the board of health of the city The court says that it found it necessary *to consider* only the question of the validity of the contract which was the basis of the plaintiff's claim The complaint showed that he was a member of the board of health—that is a public officer—and that he entered into the contract with such board for the performance of the professional services for the value of which he sought to recover in this action Such contracts are forbidden by section 5,032 of the Revised Laws of Minnesota of 1905, and are void The rule that such contracts are void and cannot be enforced rests on a wise public policy, and it must be enforced without reference to the merits of the contract, the intention of the parties, or the hardship of exceptional cases Nor does the court agree with the contention that the statute and the rule do not apply to a board of health, and that it may employ one of its members its health officer for the purpose of controlling and suppressing an epidemic of contagious or infectious disease As to the suggestion that the board of health was confronted by an emergency which justified it in making the contract in question, the court answers that an emergency confronts a board of health in every case of an epidemic of contagious or infectious disease, but this affords no reason why such cases should be excepted from the statute by the court for the board may employ, when the emergency justifies it, a physician other than one of their own number to render the extra medical services

Treatment for Rheumatism Instead of Periostitis or Osteomyelitis

The Supreme Court of Alabama affirms a judgment for the defendant in the malpractice case of Hamrick vs Shipp (72 So R 932) It says that the plaintiff's son had been thrown by a mule Some days afterward the condition developed which made it necessary to procure medical attention The defendant treated him for acute articular rheumatism Other physicians of good reputation concurred in his diagnosis and treatment There was testimony, however, which went to show that the boy's trouble was periostitis or osteomyelitis But the question put to the jury by the pleading was whether the defendant had 'conducted himself in an ignorant unskillful or negligent manner" in and about his treatment of the boy, and the trial judge instructed the jury on the defendant's request, that the question for their determination was not whether the boy had periostitis, osteomyelitis or rheumatism, but whether the defendant was possessed of reasonable skill, and whether he had been reasonably diligent, not negligent, in diagnosing and treating the case There was no reversible error in giving the instruction It was perhaps not so carefully limited on all sides as it might have been, for it seemed capable of the interpretation that it was not for the jury to determine the nature of the boy's ailment for any purpose, whereas, if the jury could have decided that question, that decision would have been of consequence in determining the ultimate question proposed by the pleading But there is no rule of responsibility which requires the physician to be infallible in the diagnosis or treatment of diseases The fact, therefore, if it was a fact, that the disease was something other than rheumatism, was evidential merely, not conclusive The instruction given correctly stated the ultimate question to be submitted to the jury for decision If the plaintiff apprehended prejudice from lack of further statement, he should have supplied that element by an explanatory instruction

Wrongful Attempt to Discredit Physician as Witness

The Springfield (Mo) Court of Appeals says that in the personal injury case of Dent vs Springfield Traction Co (129 S W R 1044) counsel for the plaintiff said in his opening statement that one Dr R would not be called as a witness because he was the physician for an employe of the defendant, he having attended the plaintiff as a physician when she was first injured It was, perhaps, the privilege of the plaintiff not to call her physician as a witness, but the remarks discrediting him beforehand may have been prejudicial to the defendant Such a statement, under the circumstances, justified the application of the defendant for the appointment of a physician by the court to make a physical examination as to the extent of the plaintiff's injuries Especially might this be considered true because the defendant could not use Dr R as a witness—he being privileged—should the plaintiff object to his testimony. And it may be considered one thing to waive your own privilege and quite a different proposition to make a statement to the jury implying that you are constrained to do so by reason of some act or conduct imputable to the opposite party

But when the trial court showed its willingness to have a physician appointed in this case to make the examination the defendant sought to name the physician, suggesting one of its own employes, and afterward named another physician The court however refused to appoint either of those named; but, without suggestion from either party, named a certain Dr S, a reputable physician and surgeon, to make the examination No objection to his qualifications were made by the defendant at any time, and no bias or prejudice was claimed, the only objection being a mere statement of the defendant's counsel that the personal relations between Dr. S and himself were not pleasant This certainly was not a sufficient disqualification to prevent the physician from making a correct examination and properly discharging his professional duty, and the objection to the action of the court is held wholly unsubstantial

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below

Medical Record, New York

December 9

1 *Case of Sulphemoglobinemia T W Clarke Utica, N Y, and R M Curtis, Paterson N J
2 Chemical Problems in Diabetes A Magnus Levy, Germany
3 Occupation as a Therapeutic Agent in Insanity M D Neff Brooklyn
4 Ventilation of Cars W A Evans Chicago
5 Diagnosis and treatment of Osteal Tuberculosis without Abscess Formation B Holmes
6 Treatment of the More Common Diseases of the Skin E L Cocks, New York

1 **Sulphemoglobinemia** —To the seven cases of this disease now recorded in the literature, Clarke and Curtis add another The patient, a woman 24 years of age, had never been robust, having suffered from most of the ills to which woman is heir A few days previously she had noticed that her lips had become blue and her color ashen, though she herself did not feel ill She was somewhat weak and markedly constipated Her appearance at that time was much as it is to day Her skin was of a steel blue, and her lips purple black The general appearance has been described as being cadaveric, or better as of the ghastly hue seen in a person standing under the Cooper Hewitt mercury light Physical examination was, however, negative except for the remarkable discoloration of the entire body The heart and lungs were practically normal The patient was observed for some weeks, and as the ordinary blood examination failed to reveal any polycythemia or other abnormality to account for the condition, a tentative diagnosis of sulphemoglobinemia was made Two cubic centimeters of blood were withdrawn from a vein in the arm The blood, which was of a rich chocolate color, was shaken with twice its volume of distilled water in order to lake the corpuscles, and then filtered several times to remove all of the corpuscular remains and fibrin, and give a clear solution This solution then being further diluted with distilled water was examined with a small pocket spectroscope and showed an intensely dark absorption band in the red portion of the spectrum in the situation characteristic of the band of sulphemoglobin Artificial solutions of sulphemoglobin made by the passing of sulphuretted hydrogen through laked and diluted dog's blood and of methemoglobin by adding potassium ferricyanid or sodium nitrate to similar blood were made for comparison

The methemoglobin solution when mixed with oxyhemoglobin showed the two absorption bands of oxyhemoglobin in the yellow and green portions of the spectrum, and the characteristic methemoglobin band deep in the red much nearer the C than the D line. The artificial sulphemoglobin showed also the bands in the yellow and green, and a band in the red, but not so far in the red as in the methemoglobin spectrum, the band being midway between the C and D lines. The patient's blood in a concentrated form showed complete obliteration of the oxyhemoglobin bands, and the presence of an exceptionally clearly defined band half way between C and D absolutely indistinguishable from that of the artificially made sulphemoglobin.

From the evidence at hand, the authors conclude that this is an undoubted case of sulphemoglobinemia of idiopathic origin.

7. **Iodin.**—In Woodbury's opinion iodin is the long desired ideal disinfectant and antiseptic. It is cheap, easily obtainable, can be carried in small bulk, is efficient in high dilution, does not damage tissue even where its vitality has been much reduced by traumatism or infection, it has been invariably successful as a germicide under all conditions when the drug and the germs have been brought together, and though it has great powers of tissue penetration the writer has yet to see a case of poisoning even when it was mopped in full strength on the peritoneum and in the parturient uterus. It can be used to disinfect the area of operation without previous preparation; to sterilize instruments, suture material, dressings, and the hands of the surgeon, during the time that the patient is going under the anesthetic. Woodbury prefers to boil his instruments when he can, as the continued use of iodin tarnishes and affects the cutting edges requiring whetting often, though the same in a lesser degree may be said for the soda solution. He uses it entirely to prepare his hands and finds it rarely causes irritation. It can be removed from the hands by boiled or raw starch, ammonia water or the aromatic spirit of ammonia, hydrogen peroxid, Fowler's solution, or ether. It is advisable where long periods of operating are expected, to dip the hands in iodin and immediately decolorize with ammonia; rubber finger cots or rubber gloves may be slipped on, and then redipped in the iodin. This is merely to protect the operator's hands from being dyed a deep brown, which is almost impossible to get rid of, especially when the tincture is reapplied every one or two days.

The solution of one teaspoonful of the tincture to the quart of physiologic salt solution is, roughly, a dilution of seven milligrams in one hundred cubic centimeters, or .007 per cent., and in this strength is most efficacious as an irrigation in all inflammatory and catarrhal conditions of mucous membrane. It can be used in the eye for the ordinary forms of conjunctivitis with prompt improvement. He has also found it to be very efficacious in acute urethral gonorrhea in twice and three times this strength. When a case of mumps developed in a company of infantry this solution was supplied to the company to be used copiously as a gargle for several days. No other case of mumps developed. It is a routine treatment for all acute throat affections, and in cases of amygdalitis the tonsils are also mopped once daily with the tincture and Bier's treatment with a rubber bandage around the throat has cut down the illness to an average of five days on sick report. It will promptly abort colds when used as a spray. Woodbury has found the iodin salt solution is excellent in cystitis acute and chronic, and catheters kept in the tincture and then transferred to this solution just before use are sterile, non-irritant and perfectly pliable.

The troublesome cases of chancroids with suppurative inguinal adenitis which drag along in hospital for so many weeks are now rapidly hurried to convalescence by a vigorous pursuit with the tincture. Buboes which have already broken down promptly become healthy granulating wounds and heal up without further trouble.

21. **Cardiac Diseases.**—Succinct reference is made by Abrams to the employment of drugs in the diagnosis of some affections of the heart.

Heart Reflex: The reflex in question is a contraction of the myocardium of varying duration when the skin of the precordial region is irritated. This reflex may also be discharged by irritation of the mucous membranes, psychic influences and percussion of the muscles, but the most effective method of provoking it is by means of concussion of the spine of the seventh cervical vertebra. Atropin paralyzes the motor endings of the vagus. During the full physiologic action of the drug the heart reflex is abolished. Small doses of pilocarpin are antagonistic in their action to atropin. After an hypodermic injection of pilocarpin (gr. 1/10), one notes an exaggeration of the heart reflex.

Adams-Stokes Syndrome: Heart-block is caused by lesions of the auriculo-ventricular bundle, and there are also neurogenic forms of the disease due to overstimulation of the vagus. The use of atropin removes the block in the neurogenic forms, whereas in the myogenic forms the heart-block is unaffected. Partial heart-block may be provoked by the inordinate use of digitalis.

Tachycardia: Aconite (tincture is most reliable) slows the heart by vagus stimulation and has only a slight action on the myocardium. If aconite slows the pulse in tachycardia, diminished tonic activity of the vagi may be assumed to exist. If atropin is used between the attacks of paroxysmal tachycardia, and no attack ensues, one may conclude that paralysis of the vagi is not responsible for the paroxysms. In tachycardia from vagus paralysis, the heart does not respond to digitalis because the latter ordinarily inhibits the rapidity of cardiac action by stimulation of the vagi. Here strophanthus is more effective, because it slows the heart by direct action and not by vagus stimulation.

Arhythmia: Vagus stimulation not only slows the heart-rate, but may also create irregularities in rhythm. If this vagus influence is eliminated by atropin, the irregularities will disappear and thus the neurogenic nature of the irregularity is demonstrated. Irritation of the mucosa of the nasal septum opposite the middle turbinate bone will evoke an arhythmia of vagal genesis. Here the irritation is conveyed indirectly to the vagus by the trigeminus. If the nasal mucous membrane has been cocainized, irritation of the mucosa by means of a probe will not evoke arhythmia. Cocainizing first one and then the other side of the nose, the source of irritation may be localized and by correcting the nasal anomaly the arhythmia may be cured.

Myocardial Diseases: Myocardial disease may be suspected even in the absence of cardiac signs, when symptoms not unlike those which accompany the broken compensation of valvular diseases present themselves. A reliable preparation of digitalis may solve the difficulty; if, after five days, the symptoms are not relieved and there is no rise of the peripheral arterial tension nor increased strength of the pulse, the drug can do no good and may even be dangerous Within thirty six hours after the use of a reliable preparation given in adequate doses, one finds that the pulse becomes stronger, more regular and slightly decreased in frequency (provided the pulse was accelerated before the use of digitalis) and diuresis is augmented By estimating the quantity of urine excreted one is afforded a guide in a dual direction the reliability of the drug and the efficiency of the cardiac muscle In cardiac muscular insufficiency, the quantity of urine may be diminished by one half or more Owing to the delayed action of digitalis, an increase in the quantity of urine does not occur until the second day of its use, then it continues to increase day after day until the normal is attained (1,500 c c in twenty four hours in a healthy adult), at this time, and when the pulse frequency has been reduced and the tension is increased, one should withdraw the drug, reduce the dose, or give it less frequently

Cardiac Asthma Dyspnea resembling this affection may be excited by irritation of the nasal mucosa, and here cocain applied to the latter by arresting the attack establishes the diagnosis In differentiating cardiac from bronchial asthma, the former may be prevented by cardiotonic medication, whereas bronchial asthma is uninfluenced unless a dilated right ventricle complicates the disease Acute failure of the ventricles is commonly present in cardiac asthma, and the attack may be at once jugulated by concussion of the seventh cervical spine Râles are usually absent in cardiac asthma unless complicated by lung edema Amyl nitrite inhalation causes the râles due to bronchial spasm to disappear and is without influence on the râles caused by mucus or fluid in the bronchial tree

Ventricular Dilatation In differentiating this condition from a pericardial exudate, the heart reflex is invaluable If the area of precordial dulness is modified after cutaneous irritation, cardiectasis and not an exudate is present

Angina Pectoris The pains of false angina are at once subdued by sufficiently large doses of antipyrin, whereas in true angina there is no relief, in fact, the pains may be accentuated, owing to the internal vasoconstriction of the drug

Thyroid Heart The physiologic tonus of the vagus is said to be dependent on the thyroid secretion In diminution of the latter (hypothyroidism), symptoms of cardiac weakness are present Disturbances due to hyperthyroidism are not common In hypothyroidism (Basedow's disease), antithyroidin or the antiserum of Beebe may improve the condition It is well to know that the cardiac signs of the latter condition are accentuated by ten 5 grain doses of a reliable thyroid preparation Iodothyrin or iodin will act in the same way and intolerance to iodin is an early sign of hyperthyroidism A biochemic evidence of the latter is the antagonism existing between thyroid extract and epinephrin in the pupillo dilator action of the latter on the eye of the frog In the normal epinephrin does not dilate the pupil, but this occurs after extirpation of the pancreas, in pancreatic insufficiency, diabetes and Basedow's disease The foregoing susceptibility is most probably caused by hyperthyroidism

Cardiac Murmurs Cardiomuscular murmurs dependent on the delirious condition of the organ disappear after the use of digitalis The latter drug also causes the disappearance of the murmurs of a relative valvular insufficiency The loudness of a murmur is largely dependent on the activity of the heart Faint murmurs may often be converted into loud ones by increasing cardiac activity and the latter may be attained by digitalis Anemic cardiac murmurs disappear after the use of an appropriate chalybeate, but it must completely disappear before we are justified in concluding that it is hemic, insomuch as anemia may coexist with an organic murmur

22 **Functional Psychiatry**—The keynote of what White terms the new functional psychiatry is its distinctly individualistic trend, its emphasis of the importance of individual psychology The new movement emphasizes so much more the necessity of the analysis of the symptoms in the individual case that in spite of the work of the Kraepelin school in this direction, White thinks it proper to designate individual psychology as the characteristic of the new movement in contrast to the life history conception underlying the Kraepelinian The fundamental conception of this new individualistic viewpoint is that every psychic fact must have been preceded by an efficient psychic cause Ideas, or better, mental states, do not arise *de novo* They must be the outcome always of other mental states from which they necessarily issue This is true throughout the world of psycho pathology, even in the realm of the so called organic—the psychoses associated with well defined brain changes That an alcoholic should have delirium may well be dependent on a toxemia, but whether he sees in his delirium snakes or monkeys, visions of his office or of hell, must depend on purely psychic causes, on the pre existing psychic material which has become involved in the disorder Whether a paretic is exalted or depressed, whether the exaltation is largely erotic or expresses itself by delusions of great wealth must find its explanation in the mental make up of the person afflicted, and the character of his psychic trends The fact intended to be emphasized is that the disease process can only deal with the material it finds at hand or which is furnished it, and which it does not itself create

23 **Adventitious Murmurs**—Benedict's patient had Banti's disease with marked ascites The apex beat was noted in the fourth interspace, just inside the nipple The cardiac area, determined by auscultatory percussion and by Benedict's modification of that method using a tuning fork instead of percussion, extended to the second space and, while not abnormally large, was tilted upward to the left and downward to the right There were no valvular murmurs, but clear, though not very forcible, valvular clicks at all valves There was a rather prolonged sound accompanying the first heart sound, to which Dr Solis Cohen's designation of "crunching" applied nicely Benedict's interpretation of the phenomenon was that the heart, crowded up by the ascites and tilted so as to strike still more forcibly against the left lung, produced an audible current of air from the vesicles into the bronchial tubes, somewhat analogous to that obtained in percussing to elicit the cracked pot sound The volume of air involved was, of course, not enough to produce an appreciable expiration, and it could not be made out that the crunching sound was increased either during expiration when the cardiac compression was unresisted, or during inspiration when we might suppose that the resisting air current would have intensified the sound On the contrary, the inspiratory and expiratory breath sounds interfered with the clear perception of the cardiac crunch However, respiration, unless very gentle, also interferes with the cracked pot sound

Benedict has noted the same phenomena in several other cases in which it might be supposed that the apex beat would have an unusually direct compressive action on the lung Among these causes are mentioned ballooning of the intestine or particularly of the stomach, and unduly vigorous cardiac action, either with organic hypertrophy or due to functional causes Cardiac displacement, adhesions tying down parts of the lungs so as to offer special local resistance to the apex beat, small effusions, etc might also be expected to give rise to the same phenomenon Another adventitious sound in connection with the apex beat is of fairly common occurrence With the stomach distended, either spontaneously or artificially, especially when the contents are mainly gaseous, the cardiac impact is almost always appreciable The stomach tube, with a funnel inserted, makes a very good monaural stethoscope, and one can hear very interesting sounds, as of gastric contraction (manifested by the churning of the contents, scarcely the muscular movement itself), the effervescence of a bicarbonate if the contents are strongly acid, the effervescence produced with hydrogen peroxid, etc The respiratory and cardiac sounds are usually audible to some degree through the stomach tube Aside from the detection of the cardiac impulse with the stomach tube in place, the first heart sound of its accompanying systolic murmur, is pretty regularly transmitted to some degree over the area of a distended stomach

In quite a number of cases Benedict has been able to map out the gastric area by auscultatory percussion, with the patient's own heart acting as an assistant to furnish the percussion. In some instances, there is purely a transmission of a heart sound, valve closure or murmur, as the case may be. In others, the apex beat either starts a wave in the liquid contents of the stomach, or seems directly to force a little air or liquid through the orifices, mainly the pylorus, or reflexly produces peristalsis which, in turn, may cause a sound in either of the ways just mentioned. Thus gastric sounds, corresponding to the heart beat, may be a mere thump, a crunch, swish or indescribable murmur.

41 Status of Trachoma in Philadelphia. C. P. Franklin, Philadelphia.
42 *Galactagogue Action of Infundibulin. I. Ott and J. C. Scott, Philadelphia.

40. **Migraine in a Family.**—The study of the family history given by Price is of interest because of: 1, the remarkable prevalence of migraine; 2, the unusual sensory manifestations in several of the cases, and, 3, the association of epilepsy with migraine in one case. A man, aged 21, complained of violent headaches occasionally preceded by numbness of the right side of the body. He stated that the headaches had occurred paroxysmally several times a year since he was six years of age, the longest interval between the attacks having been six months. The headaches occur, as a rule, in groups of three of six in rapid succession; thus, if he has one attack, he is apt to have more, and, if he has the fourth attack, he expects them to continue until he has had six. Many of his attacks are preceded by numbness and hypesthesia, commencing in the toes, and creeping up until they affect the leg, arm, trunk, face and tongue. He stated positively that these symptoms are most marked in the hand and foot, becoming less toward the proximal portion of the extremities, being very slight over the trunk; they are present to a marked degree, however, in the lips and tongue. At times he has been unable to control the movements of the affected arm and leg. The numbness lasts from twenty minutes to one hour, and is followed by severe headache on the side opposite the numbness, lasting from twelve hours to three days. Other attacks are preceded by visual disturbances; everything will look as if moving around in a circle; blurring of vision; hemianopsia. The paroxysms are always preceded by pallor and usually accompanied by vomiting, followed by relief of the headache. There is no history of unconsciousness. The grandparents, as far as could be learned, were free of any nervous condition. On the maternal side, the history is negative as to migraine, epilepsy or insanity.

On the paternal side, one aunt has severe attacks of migraine. Another aunt suffers from migraine but not severely. A third aunt had St. Vitus's dance when a child, and in adult life was exceedingly nervous. An uncle acted peculiarly, and was said to have "softening of the brain." The father, aged 67 years, suffers from attacks of blindness for a few seconds, then numbness of arm, tongue and lips, followed by severe headache. At times his speech is affected to such an extent that the family cannot understand what he is saying. The rest of this generation, thirteen in number, all reached adult life, but were free from any nervous disease. In the present generation there are eight children; seven have migrainous attacks, and three have marked numbness affecting one-half of the body.

42. **Galactagogue Action of Infundibulin.**—In the goat the authors found in the early nursing period that infundibulin injected into a vein in the ear rapidly and greatly increases the flow of milk. The nipple had a cannula inserted into it, and a water aspirator produced the suction necessary to empty the udder. The milk aspirated before and after the injection was caught in a graduated flask and measured every five minutes. This increased flow of milk is not due to an increased amount of blood in the udder, as infundibulin contracts the arterioles. This fact, the authors state, can be correlated with the increased size of the pituitary in pregnancy, although in these cases the enlargement is chiefly in the anterior lobe.

50 *Relation of the Medical Profession to Medical Institutions and the State. M. T. Sudler, Lawrence, Kan.

50. **Relation of Medical Profession to Medical Institutions.**—Sudler believes that the medical profession of Kansas is overcrowded, and that unqualified and poorly educated men have been admitted to the profession and lowered it in the estimation of the public. This has fostered irregular practitioners such as osteopaths, chiropractics, christian scientists, etc. At present public charity is dealt out without any plan or organization. This is wasteful. The state should organize its hospitals and schools with definite relation to the needs of the people and the profession. The state should provide laboratories where pathologic and bacteriologic examinations can be made at moderate cost. As a matter of economy students can be instructed in these same laboratories. The state should maintain hospitals which would relieve physicians from doing charity work as far as possible. Before entering on the practice of medicine Sudler would ask that every candidate should have had at least two years of college work. Then four years in the medical school, and finally be required to pass an exhaustive practical examination.

62 **Reasons Why Prescriptions Fail.**—Brumby reviews some of the phases of the patent and proprietary medicine evil and urges physicians to familiarize themselves with the United States Pharmacopeia and the National Formulary He endorses the work of the Council on Pharmacy and Chemistry.

63 **Cataract Dressing.**—Thompson uses a crinolin bandage over the regular bandage and dressing. The only new thing about this bandage is the technic in its application whereby the ears are prevented from coming in contact with the bandage when dry This dressing fits snugly and has a feeling of protection When it is removed on the second, third or fourth day, the crinolin portion over the face and eyes can be used as a mask externally by attaching tape and fastening around the head over the other dressing, or internally by placing next to the moist gauze and applying bandage over it The absolute protection from external violence, as well as the complete immobilization of the eye and its appendages, renders this, in Thompson's judgment, one of the very best cataract dressings If properly applied he firmly believes that it will keep many patients from infecting the eye by innocently meddling with the dressing

Thompson has for a number of years, in cases of entropion, been doing an operation in part after Greene and Holtz with a modification of his own The operation is as follows An incision is made on the inner surface of the lid, in a line parallel to and about 2 mm distant from the row of openings of the Meibomian ducts It is carried through the conjunctiva and whole thickness of the tarsus, and should extend, in cases of complete entropion, from the inner to the outer canthus An incision is next made through the skin about 2 mm above the lashes, in operations on the upper lids, extending from the inner to the outer canthus By a dissecting process the upper margin of this skin is elevated to a point above the upper border of the tarsus, which is exposed at three or four points by cutting out sections of the muscle and sutures, three or four in number, are passed through the skin of the lower margin of this cut with curved needles at points corresponding to the exposed portions of the tarsus, and with the assistance of forceps the sutures are anchored into the upper portion of the tarsus by passing the needles partially through it The sutures are then tied, care being taken to see that the cut edge of the skin comes in contact with the exposed areas of the tarsus Material assistance can be had by placing a small probe or the end of a pair of forceps beneath the suture and making gentle pressure while the knot is being tied The portion of skin which has been elevated by dissection is left free Best results are obtained by seeing that the upper margin of this skin remains free until the lower margin is attached to the tarsus The advantages of this over other operations is two fold first, the piece of skin from the lashes to where it is united to the tarsus is so short that it is not liable to stretch, thereby allowing the margin of the lid to again turn in, second, there is no sacrifice of integument, for that reason rendering the operation harmless in so far as the welfare of the lids are concerned

4 **Radium Therapy in Eye Disease**—After an investigation into the possibilities of radium as a therapeutic measure in eye disease, the authors, A Lawson and J M Davidson, concluded that radium is likely to prove of great service, both in the treatment of external diseases of the eye and in those of the eyelids The method of applying the radium was crude, but satisfactory The eye was first cocainized and the radium, which was contained in sealed glass tubes, permitting only the passage of beta and gamma rays, was applied directly to the affected part The fingers of the operator were protected by enveloping first that part of the tube not required and then the fingers in a thick, continuous wrapping of lead foil In no single instance did they observe the slightest ill effects from the use of radium, no increase of inflammation or aggravation of symptoms occurred in any case, with the one exception of pain It soon became evident that lesions of the cornea could be treated successfully with this time limit of five minutes by the same dose which, for affections of the skin and lids, required an exposure three or four times as long, and also that superficial lesions of the cornea frequently do not need any more than quite a small dose, such as 5 to 10 mg, applied once or twice as the case might demand With regard to the frequency with which the exposures were repeated, they were guided entirely by the progress or otherwise of each individual case When dealing with a virulent and highly dangerous process, such as a hypopyon ulcer, it was obviously necessary to get a result with the least possible delay, and consequently the exposure was repeated as soon as considered safe, if no improvement had been noted, whereas, in milder cases, they were content to wait longer for signs of amelioration, being anxious to find, if possible, the minimum number of sittings necessary to effect a cure The effects of radium are continuously exhibited for a considerable space of time, extending into a matter of six weeks at least, and so some of the cases had only one sitting, and a perfect cure resulted The margin of safety with regard to the minimum interval that should elapse between the sittings must obviously depend on the dose employed The larger the dose, the sooner should its effects be produced, and the longer the interval between the sittings Consequently, if a large dose was considered necessary at the first exposure they seldom repeated it with less than a week's interval, except it happened to be noted that the disease continued to spread in

spite of the treatment, in which case they considered that a second exposure might safely be given at a rather shorter interval

5 **Serum-Anaphylaxis**—The chief point of interest in Sloan's case of diphtheria was the occurrence of sudden collapse after the injection of serum at the onset of the second attack Sloan has no doubt that the grave condition was due to serum anaphylaxis (1) The collapse occurred within two hours of the injection without other apparent cause and while the child was lying quietly in bed, (2) the collapse was accompanied by the almost simultaneous appearance of a marked serum rash of the urticarial type Apart from the twenty four hours' urgent illness following the injection, the prolonged febrile period thereafter and the slow convalescence were chiefly due to the serum phenomena It is Sloan's opinion that, until we have more accurate knowledge of the circumstances bringing about anaphylaxis, we should be particularly cautious not to inject foreign serums without good reason, because we may by doing so render our patients so sensitive that a future necessary injection may cause grave consequences

24 **Pulmonary Tuberculosis**—In November, 1909, Lees published the details of the method of treatment employed by him, and narrated thirty cases of incipient or early pulmonary tuberculosis in which it had been employed with success Now he records the present condition of these cases, and adds an account of twenty subsequent cases in which the same method of treatment has been used The thirty cases reported were all incipient or comparatively early cases, though three or four of them were very acute and rapidly advancing when the treatment was instituted In every one of these thirty cases the result is highly satisfactory Some of the twenty additional cases now reported came under treatment at a much later stage of the disease or were attended with grave complications In such instances recovery must be comparatively slow, and the final issue may be doubtful Any case of pulmonary tuberculosis, if allowed to progress unchecked for many months may easily reach a condition which is incurable by any form of treatment But Lees' contention in these two papers is that this ought never be allowed to happen Pulmonary tuberculosis is recognizable and ought to be discovered before there is any breaking down of lung tissue To suspend the diagnosis until tubercle bacilli are detected in the sputum is like delaying the diagnosis of cancer until the glands are involved

25 **Fractures in the Neighborhood of Joints**—Jones pays more attention to function than appearance, considers correct alignment of more importance than meticulous care in reposition of fragment believes that pain is always an indication for physiologic rest, and therefore deprecates early forced passive movements

26 **Potassium Bichromate in Treatment of Phthisis**—Six cases of phthisis treated by the internal administration of potassium bichromate are reported by Tombleson He gives the potassium bichromate in doses of ¼ gr (2½ minims of a 10 per cent solution in water) either alone or in a tonic mixture (phosphate, hypophosphite, or simple iron), such dose to be taken in a wine glass of water after food, at first twice and later three times a day The first dose and possibly the second may cause vomiting, but this does not matter, as, in his experience, toleration is easily established without missing a dose The color of some of the mixtures changes from yellow to green, but this seems in no way to impair the efficacy of the mixture Of these six patients the last four do not know they are under any special treatment. Improvement has been noticeable after the expiration of the first fortnight of treatment.

37 **Syphilitic Rachitis and Wassermann's Reaction.**—Leroux and Labbé found the reaction positive in the fourteen cases of rachitis reported whenever there were manifestations of virulent inherited syphilis In the cases in which the reaction was negative there were only dystrophic and rachitic malformations without any virulent manifestations The findings confirm the assumption that rachitis may have a syphilitic origin, yet it is not of a syphilitic nature, syphilitic rachitis seems to be mainly the result of the dystrophic influence of inherited syphilis It is probable that any chronic infection or intoxication occurring at a certain period of ossification may be an efficient cause of rachitis It has been observed after malarial infection in infancy and in diabetic infants

39 **Continuous Lumbar Drainage**—Rosenthal gives an illustrated description of the needle which he uses for lumbar puncture, and the sheath which is left permanently in the opening for continuous drainage Gorse has reported the cure of a patient with suppurative meningitis, the treatment including this permanent lumbar drainage kept up for thirteen days

44. **Tubal Pregnancy.**—Fehling reviews his experience with 300 cases of tubal pregnancy in which he operated. In his latest series of 170 cases none of the women with tubal abortion succumbed, but seven died in the fifty cases of rupture of the gravid tube; of this number five died within two hours of the operation, the condition not permitting recovery; one died of yellow atrophy of the liver without peritonitis and the seventh succumbed to peritonitis resulting from an operative injury of the intestine. Only 12.4 per cent. of the patients had not borne children before. In 52 per cent. of the patients the other adnexa were more or less pathologic. The extra-uterine pregnancy occurred more than once in five of the cases. The interval between the last pregnancy and the extra-uterine averaged over four years and ranged up to sixteen. He comments on the rarity of extra-uterine pregnancy in private practice, having encountered only 10 cases among 1,000 private obstetric patients.

50. **Curability of Cancer Under Palliative Measures.**—Bretschneider declares that the prognosis of cancer in the so-called hopeless cases should be guarded, as instances are not lacking in which an apparently incurable growth subsided under merely palliative measures. He reports a typical case of the kind, a woman of 53 having a supposed inoperable carcinoma of the uterine cervix, but it was so favorably influenced by repeated palliative operations that at present there is not a trace, either macroscopic or microscopic, of malignant disease at the spot, and the metastatic foci have evidently been arrested in their growth and have partially retrogressed. The general health of the patient is normal and she has no disturbances of any kind. The clinical cure is thus complete, although she still carries numerous cancer foci; the carcinoma cells seem to have lost their proliferating capacity and the foci have become latent. When first seen, suspicion of kidney disease and dilatation of the left ventricle complicating the inoperable adenocarcinoma rendered the outlook very grave. After curetting and cauterization with 50 per cent. zinc chlorid there was some collapse, requiring camphor and heart tonics, but the patient was dismissed from the hospital in two weeks. She returned seven months later in very good general condition and the cancer had materially subsided. The same technic was applied again and with good results. Four months later she returned on account of hemorrhages and the cancer was then deemed operable, but at the laparotomy the peritoneum was found studded with cancerous nodules, and nothing further was done, as the diffuse peritoneal carcinosis had destroyed all hope of success. The cervix cancer was merely curetted and cauterized as before. A year later, two years after the first excochleation, the patient was seen again, and the aspect was that of perfect health for her age, 55. There had been no further hemorrhages, and the cervix presented merely the usual senile aspect. There are no records, he adds, of the necropsy findings in such cases of unexpected clinical cures of cancer, but there is nothing theoretically to prevent the assumption that carcinoma foci may completely retrogress. There is evidently a constant battle between the defensive forces of the organism and the proliferating forces of the carcinoma cells. Changes in the blood, as after fever or profuse hemorrhages, and possibly after deep cauterization of the focus, seem to exert sometimes a favorable action on the malignant foci. When the balance between the defences and the cancer cells is maintained and neither is victorious, the cancer is kept in a latent stage, but at any moment when the defensive forces are weakened by any cause the cancer may get the upper hand. Such an assumption would explain the late recurrences of cancer after a long period of latency. The case reported, and others on record, indicate that the defensive forces of the organism are powerfully seconded in their struggle with the cancer cells when the latter are vigorously cauterized or are affected in some other way. There are evidently factors still unknown to us at work in these cancer cases, and something is liable to turn up that will unexpectedly diminish the proliferating capacity of the carcinoma cells and thus induce a turn for the better. Such a possibility should always be borne in mind in the management of inoperable cancer, and the prognosis should not be so grave as to drive the patients into the hands of quacks, especially as the latter are liable here and there to get the credit of the unexpected turn for the better which may occur at any moment.

51. **Forensic Importance of the Lacteal Secretion.**—Hertzsch concludes from his research on fifty cases that the absence of colostrum-corpuscles indicates that the child was viable but not necessarily at term. The presence of colostrum-corpuscles alone is no criterion for determination of the date of delivery or age of the fetus or whether the child was suckled or whether this is the first pregnancy or not. If the breasts secrete ripe milk the presence of colostrum-corpuscles does not conflict with the assumption that the child was born at term. In a case of supposed infanticide he certified that a viable child had been born, basing his statement on the copious supply of ripe milk free from colostrum-corpuscles or other formed elements, and circumstances later confirmed the correctness of his testimony.

53. **Twenty-Three Years of Gynecologic Operations.**—This issue of the *Archiv* is a *Festschrift* on the occasion of the centennial of the university clinic for women at Leipsic. Zweifel reviews the 4,062 laparotomies, and devotes a hundred pages to detailed study of technics and results.

54. **Ultimate Outcome of Abdominal Hysterectomy for Cancer.**—Aulhorn compares the outcome with various technics in 420 cases of carcinoma of the uterus during the last eight years; in 221 other cases the growth was inoperable. In the operative cases there were nine women who had never borne children, while the rest averaged six children apiece. Of the 255 patients operated on over six years ago, fifty-two have had no recurrence to date, that is, 51 per cent. according to Winter's formula. Recurrence in the fifth and sixth years was observed in two cases.

64 Index of Hardness of Roentgen Tubes. (Objektiver Härtemesser mit Zeigerausschlag für den Röntgenbetrieb.) H. Bauer.

58. **Treatment of Laryngeal Tuberculosis.**—Schröder has had 416 patients with laryngeal tuberculosis in his care during the last fourteen years and the course of sanatorium treatment for each averaged 140 days. He estimates the frequency of laryngeal tuberculosis as a complication of chronic pulmonary tuberculosis in 20 per cent. of the cases in which sana-

torium treatment is indicated, and he urges careful examination for it in every case of lung trouble Institutional treatment is advisable, as the general treatment is the main thing; only as the lungs improve and heal is there prospect of the laryngeal process healing Appropriate surgical measures may prove useful adjuvants, but tuberculin treatment should be instituted with extreme reserve and caution A relative cure was obtained in 24 per cent of his 416 cases, but only in 15 2 per cent of the 308 febrile cases and in 19 per cent of the "open" tuberculous cases

61 **Saline Infusion in Eclampsia**—In the case reported by Frankenstein the eclampsia developed during labor and the convulsions persisted after delivery No benefit being apparent from narcotics, 1 liter of salt solution was injected subcutaneously, repeated six hours later, after which there were no further convulsions, fifty minutes after the second infusion copious diuresis set in and the patient was cured Notwithstanding the fine results in this case he thinks it would be better to use a 4 per cent sugar solution or hypotonic salt solution, the ordinary salt solution is liable to make too many demands on the kidneys in their morbid condition Hypotonic solutions are compensated by the hypertonic composition of the blood He has had ample experience in regard to the harmlessness and the usefulness of a 4 per cent sugar solution in his operative gynecologic work The subcutaneous route is necessary in eclampsia, as there is no time to waste on intestinal infusion, but physiologic salt solution, he declares, should be banished from the treatment of eclampsia, with impending or actual heart failure any infusion is perilous

63 **Roentgen-Ray Treatment of Myoma**—Schindler reports continued and repeated success with this method of treating myoma, giving the details of three cases Under the exposures the complicated myomas are transformed into harmless small tumors, and by the menopause induced the cure is completed until scarcely anything is left of the myomas The objection that the relics of the myoma might be the seat of malignant degeneration later applies equally well to other measures such as castration The Roentgen ray treatment spares the patient the laparotomy and, he says, is entirely harmless, so that one is justified in giving the method a trial, at least, before resorting to an operation In the case of a woman of 50, a myoma the size of a child's head with excessive menstruation subsided one half in size and the menopause came on under eleven exposures in three weeks, with four exposures later

66 **Deforming Arthritis in the Young**—Perthes believes that the frequency and importance of deforming arthritis of the hip joint in the young have never been sufficiently appreciated, he had no less than six cases of it last year Trauma can rarely be incriminated, in one of his cases there had been a suppurative process in the hip joint in infancy, but the symptoms of the deforming arthritis did not develop until a number of years later Pain and tenderness in the joint are rare, although long walking may induce spontaneous pains which may be experienced in the knee but in many cases there is no painfulness at any time The limping gait is due probably to insufficiency of the abductor muscles In all the cases that have been studied to date, (twenty six unilateral and twelve bilateral) the course of the pathologic changes was always slowly progressive, but the interference with movement and the spontaneous painfulness may grow less for a time In treatment, systematic massage and exercises, especially of the abductors, are recommended and immobilization warned against With much deformity of the bone operative correction may be advisable The details of the thirty eight cases on record are summarized

70 **Improved Technic for Extension with Fracture.**—Wildt calls attention to the importance of counteracting contraction more than is possible with the ordinary Bardenheuer technic, especially after the adhesive plaster has loosened up a little He describes the technic with which he accomplishes this by interposing a rubber strip in the plaster where it passes over the fracture The elastic strip is sewed to the strip of plaster, leaving fulness enough so the rubber can stretch by 1 cm. The adhesive plaster is then applied as usual, but where it crosses the fracture it is cut across, leaving the elastic rubber to stand the strain alone at this point

72 **Compressed Air for Massage, Etc**—Kuhn calls attention to the great therapeutic value of air under high pressure applied locally to organs, fractures etc The result is a total anemia of the part which is followed by a hyperemic reaction, inducing what he calls massage of the blood The hyperemia produced in this way is more intense than by any other means, while the action on the organs and parts of the air under high pressure is extremely gentle He applies the high pressure in a double sac in which the limb is placed the air circulating between the double walls of the sac, or a double sac is made to fit over the organ or part to be treated He states that this high pressure massage is useful as an adjuvant during and after the Bier hyperemia technic, while it is an independent method for effectually treating edema, varicose ulcers excessive callus and joint fractures The alternation of anemia and hyperemia, he states, is on a scale never before realized, revitalizing the parts and promoting absorption of pathologic fluids by its imitation of the natural stimulation of metabolism A tank of compressed air can be used but it is better to have a large amount to use more freely, and he has devised a special apparatus for compressing the air very economically in hospitals where power can be available The apparatus was described in the *Deutsche med Wochenschrift*, Aug 4, 1910, page 1445

73 **Dislocation of Tarsometatarsal Joints**—Grunert has found fifteen new cases on record of dislocation of Lisfranc's joint since Lenormant's compilation of ninety six cases in 1908, and here gives the details of them all with two additional cases from his own experience The luxation was total in fifty eight Reduction by manual pressure succeeded in only 35 per cent of the total 105 cases, but the patient got along well with the uncorrected total dislocation, while the outcome was most disappointing in the operative cases The experiences related indicate that operative interference is liable to do harm ultimately rather than good in the total luxations, but that when only a single bone is dislocated, operative interference is justified and has always proved effectual Any attempt to resect bone merely weakens the foot

75 **Extensive Saline Infusion in Treatment of Peritonitis**—Bertelsmann strives to restore approximately normal conditions in the circulation in peritonitis by saline infusion before he attempts any operation In fourteen cases of peritonitis last year, treatment was by intravenous saline infusion of nearly 4 liters of salt solution before and during the operation Large compresses were laid over the intestines when the abdomen was opened and the abdominal walls were fastened over them with silk sutures in such a way that no intestines could protrude while a broad slit was left open between the lips of the wound After the operation subcutaneous or saline infusion is continued at need up to 20 liters in the first two days By this copious flushing of the vascular system the stagnation in the peripheral vessels is combated and the heart given something to pump on, small amounts of salt solution do not accomplish this He operates in every case of peritonitis, no matter how desperate it may appear. Of the six

fatalities in his series, five were in patients practically moribund when first seen. The only death that had not been expected was in a woman who died of embolism twelve days after the operation. He suggests several queries for further research: 1. The share in peritonitic collapse of the inflammatory congestion, and whether this is to be combated or regarded as a favorable element. 2. Is the collapse during operations for peritonitis due to the fact that the blood rushes into the vessels in the abdomen when all pressure is removed from these vessels, and can this assumption be sustained by experimental research? 3. Does bacteriemia frequently accompany peritonitis? 4. Is existing bacteriemia influenced favorably or unfavorably by saline infusion?

80. **Treatment of Tuberculosis in Children with Large Doses of Tuberculin.**—Fuchs reports the application in a number of cases of Schlossmann's method of accustoming the child to large doses of tuberculin. About two months was all that was needed to bring them to a dose of 1 gm. The results were very disappointing; no benefit was realized in any instance and the impression in some cases was that the tuberculosis was directly aggravated. Injection near the focus of the surgical lesion induced a peculiar and very pronounced cutaneous reaction, evidently an anaphylactic phenomenon, peripheral to the lesion.

84. **Phosphorus and Strontium Sclerosis.**—Lehnerdt's recent experimental research shows the importance of the influence of single elements on the growth of the bones, and opens a comparatively new field for physiologic research and for explanation of the action of drugs.

88. **Syphilis of the Pancreas.**—Fey reports a case of visceral syphilis in which the symptoms from involvement of the pancreas were exceptionally prominent. The patient was a man of 42, otherwise healthy, who acquired syphilis at 21 and took five courses of specific treatment in the course of three years and was free from symptoms for nearly twenty years. Then he had an attack of what seemed to be severe influenza from which he did not seem to recover, and hectic fever, night sweats and cough suggested tuberculosis. There was occasional profuse diarrhea ceasing suddenly after five or six days and, after a year of these symptoms, attacks of pain, most pronounced in the upper abdomen, coming on independent of the intake of food and persisting for one or three hours. Annoying, persistent eructations and enlargement of the liver and spleen, with a little ascites, suggested tuberculous peritonitis. The feces at this time became clay-colored and soft, and sugar was found in the urine. The diagnosis then was changed to carcinoma of the liver, but the symptoms resisted all treatment on these bases and the patient lost nearly a hundred pounds in weight in the course of the eighteen months. Functional tests of the pancreas gave positive findings with the Cammidge and trypsin tests and the Schmidt nucleus test, while the fat content of the stool averaged 39.4 per cent. and a drop of adrenalin in the left eye induced pronounced mydriasis in twenty-five minutes. The diversity of the symptoms, the protracted course of the syndrome, the hectic fever and positive Wassermann reaction convinced Fey that syphilis was responsible for the whole trouble, and under mercurial inunctions and potassium iodid the fever disappeared in three days, the glycosuria in one week, and the liver and spleen returned to normal size in less than a month. The improvement continued to a clinical cure in a few weeks, but the persistence of the Cammidge reaction and positive adrenalin test indicate that the pancreas still has some interstitial pathologic process, although the gummas probably responsible for the severe symptoms previously observed had retrogressed. The syndrome of visceral syphilis is liable to involve the most various organs and thus present a Protean variety of symptoms, never encountered under other conditions.

89. **Convulsions in Whooping-Cough.**—In the first of Schiller's four cases, the convulsions were evidently the result of latent tetany in a female infant, 17 months old, artificially fed. The prompt success of treatment for the spasmophilic diathesis: castor oil, tea, phosphorus-cod liver oil and abstention from milk, with symptomatic measures, confirms the assumption of tetany as the cause of the convulsions, the whooping-cough having continued its course unmodified. In the second case the convulsions were merely a casual coincidence, ushering in severe varicella with otitis media. Measures directed against the fever, cold packs and aspirin, banished the convulsions. This patient was a boy of 3. In the third case the infant began to cough when 4 days old, and at three weeks the closure of the glottis initiating the cough frequently persisted, causing dangerous asphyxia from the laryngospasm. The trouble in this case was an actual complication of the whooping-cough, peculiarly dangerous on account of the suffocation recurring without warning and liable to prove fatal unless the child was watched incessantly. In the fourth case a mustard pack was applied on account of beginning bronchopneumonia in an infant nearly 2 years old, with whooping-cough for six weeks. The child was otherwise healthy, but six hours after the mustard pack, applied according to Heubner's technic, severe convulsions developed, with cyanosis, requiring artificial respiration and rapidly exhausting the child, with high fever and death from heart failure the next day. Ibrahim recently reported fatal convulsions following the mustard pack in a case of whooping-cough. If Schiller had known of this experience he would have applied lumbar puncture in his case to counteract the heat congestion from the mustard pack, superposed on the febrile tendency of the incipient bronchopneumonia.

90. **Function of the Appendix.**—Härtig suggests that the appendix may have an analogous function to the automatic lubricators in automobiles to supply a lubricant at points where it is especially needed. The little reserve of intestinal juice in the appendix may be just what is needed at the bottom of the well formed by the cecum to aid in passing the feces along.

93. **Varicocele of Pregnant Women.**—Cramer ascribes the development of varicose veins to primary changes in the walls of the vein under the influence of toxic action. Toxic action from the internal secretions is peculiarly liable to occur in

the pregnant woman and predisposing mechanical causes enhance this tendency. He has noticed that inguinal hernia in women frequently dates from a pregnancy, and he explains this by the spreading of the inguinal canal from the enlargement of the veins passing through it. The stretched canal does not retract again when the enlarged veins subside to normal size. The condition thus left favors development of a hernia. In the male, the varicose enlargement of the corresponding vein occurs outside the inguinal ring, but the corresponding varicocele in women develops in or inside the ring. Since he has been studying this subject he has found complaints of pains in the inguinal region in pregnant women much more common than he had supposed. In one case of the kind the pains were so severe and the disturbances so great that he was compelled to operate, and he gives an illustration of the varicocele removed from each side, at the sixth month of pregnancy. The external ovarian vein was as large as a man's thumb, and was stretching the external inguinal ring so that a finger could be inserted on each side of the engorged vein. There was no tendency to hernia on either side but after resection of the varicocele the tendency of the canal to gape was corrected with sutures as for inguinal hernia, and the pregnancy progressed undisturbed.

94 and 95 **Prophylaxis of Puerperal Fever.**—In the course of a discussion of intra uterine breathing, sterilization of the hands and "self-infection," Fromme reiterates that the greatest progress realized in obstetrics in the last few years is that we have learned to distinguish between puerperal infection and puerperal intoxication He regards infectious puerperal fever as the result of importation from without of virulent alien germs capable of penetrating into living tissue and thus setting up general sepsis. The putrefaction bacilli normally in every vagina are not capable of this. If alien germs from without can be kept completely away from the vagina and uterus shortly before, during and after childbirth, there will be no true infectious puerperal fever. When certain that this is the case, we can be confident that the parturient will recover without severe illness. The woman's own germs are incapable of setting up true puerperal fever, and if fever does occur it is merely an intoxication fever from retained membranes or obstruction to the outflow of the lochia, and it subsides when the substances are rinsed out which have been providing the culture material for the patient's own germs.

96. **Combined Examination.**—Sonnenfeld has found that any means to divert the patient's attention away from the examination generally suffices to induce the desired relaxation of the abdominal walls for "combined examination." He has found that a simple means to divert the attention is to have the patient hook the fingers of her two hands together and pull vigorously. This has frequently succeeded in his experience when other, more complicated measures failed.

110 Multiple Neuromas on Spinal Roots in Nine Months' Infant. R Graupner

107. **Bladder Disturbances After Use of Ehrlich's "606."**—Eitner reports a case in which an injection of "606" was followed by retention of urine and constipation with abolition of the reflexes, the clinical picture being identical with that of the two cases reported from Prague and mentioned in these columns Sept. 3, 1910, page 898. Eitner never uses methyl alcohol, so that the disturbances cannot be explained in this way, which was the explanation accepted for the Prague cases. He used for the injection a mixture of what was left in two tubes of the "606," the rest of the contents of the vials having been used in another case respectively fourteen and three days previously. The tips of the tubes were fused again to protect the remaining contents, and he thinks that the heat applied in the fusing must have modified the drug within in some way to render it more toxic. Experiments on animals with the "606" after it had been heated seemed to confirm this assumption of a toxic modification of the drug under the influence of heat.

109. **Drug Hyperkeratosis.**—In the first of Ruete's two cases, a man had taken 18 drops of Fowler's solution every day for two years; it had been prescribed originally for herpes and he had not seen a physician since. During the last year keratosis in both hands and feet had developed to a pronounced degree, the palms being covered with wart-like excrescences. The patient was otherwise in good health and free from nervous disturbances. On suspension of the arsenic the skin affection subsided, but it showed a tendency to recur if he took arsenic in any form. There was no melanosis. In the second case the hyperkeratosis was evidently of syphilitic origin and was accompanied by ichthyosis of the back, all subsiding under mercurial treatment.

124 *Defective Development of Testicles (Entwicklungsstorungen der männlichen Keimdrüsen im Jugendalter) J. Kyrle
125 *Transmission of Cretinism from Man to Animals (Uebertragung des Kretinismus vom Menschen auf das Tier.) A. Kutschera
126 Ehrlich's "606" in Syphilis G Riehl
127 Idem O Kren
128 Prostatectomy for Traumatic Hemorrhage H v. Haberer.

124 **Disturbances in the Development of the Testicles in Children.**—Kyrle found only ten apparently normal testicles in 110 child cadavers. In eighty-six cases development was extremely defective. Among thirty-nine children less than a year old, in twenty-nine the testicles showed this striking lack of normal development, showing that it was congenital. In fifty of the cadavers there were other anomalies in development. It is evident, he says, that a child born with undeveloped, unfinished testicles must be on a lower physical plane than the children with normal genital glands, according to the modern conception of the great importance of these glands for the development of the organism as a whole. He describes the histologic findings in detail, with eleven illustrations, this being, he thinks, the first research of the kind on the testicles before puberty.

125. **Transmission of Cretinism to Animals.**—Kutschera found two dogs with every sign of cretinism, including the enlarged thyroid, which were brought up in the bed with a certain pauper and her cretin children. Another dog given the family and sleeping in the same bed developed signs of cretinism in three months, and in nine months the picture of cretinism was complete. Another normal dog given the family at the same time was too large to be taken into bed

with them, and he escaped the cretinism, although he slept in the room Kutschera states that practical experience has confirmed again and again the theoretical premises that cretinism is most liable to develop in small, dirty homes among people who are lacking in a sense for cleanliness and who were exposed to frequent or intimate contact with cretins in early childhood

132 *Prophylaxis of Air Embolism with Placenta Prævia H Peters

132 **Avoidance of Air Embolism with Placenta Prævia**—Peters is convinced that fatal air embolism is more common than generally believed, especially in private practice with lack of necropsy But about a dozen cases of air embolism with placenta prævia are now on record He had a case of this kind in his own practice, the fatal embolism occurring as he was seizing the foot after version, without anesthesia, on an otherwise healthy woman with wide vagina and nonruptured membranes No means is known to avoid this danger of air embolism unless the version and separation of the placenta can be done *under water*. He thinks that this innovation might ward off all danger from this cause, but he has had no opportunity to apply it himself He suggests that the bath tub could be cleaned with boiling water and alcohol, setting fire to the alcohol, and using boiled water for the bath, no more water is needed than to cover properly the external genitals The inflatable bag could be introduced under water, and the vaginal portion of the uterus could be drawn out of the vulva, which maneuver aids materially in manual separation of the placenta, but has not been applicable hitherto with placenta prævia on account of the danger of air embolism

138 **Etiology of Endemic Goiter**—Ebbell calls attention to the fact that goiter seems to be endemic in the regions and the geologic formations where there seems to be the greatest radio activity This has convinced him that the radium emanations may be responsible for development of endemic goiter, this assumption being sustained by the fact that boiling the water, which annuls its radio activity, seems to prevent the tendency to development of goiter He has no opportunity for experimental research in this line and he asks others to give animals radio active water exclusively for a period of three months at least to determine the effect on their thyroids

140 **Tuberculosis of the Kidney.**—Johannessen accepts the possibility of spontaneous recovery from tuberculosis of the kidney—several such cases are on record, but the rarity of this occurrence does not permit reliance on it He gives the details of a number of instructive cases The subjective and objective symptoms may vary within a wide range and the tuberculous process in the kidney may run an entirely latent course for a long period, without any subjective or objective symptoms This explains why tuberculous nephritis often is not diagnosed until it has reached a comparatively advanced stage In other cases pains and hematuria bring the patient to the physician in an early stage In some cases the first symptoms are pollakiuria with frequent micturition or even incontinence Guisy noted pollakiuria as the only symptom of incipient kidney tuberculosis in six out of thirty one cases, in three cases nocturnal incontinence of urine was the first sign of trouble This may be the result of what Guyon calls reno cystic reflex action The kidney is generally enlarged, but may sometimes be abnormally small, in the beginning the kidney is not palpable as a rule In the incipient stage there may be a dull or vague pain of varying intensity and apparently spontaneous, localized in one of the lumbar regions, sometimes the sound side, or paroxysmal severe pain, radiating down to the bladder or to the other kidney or up into the shoulder The urine may be limpid and acid without albumin In one of the cases reported the urine was pathologic but the bladder seemed entirely normal In another the severe pains were localized in the left side while the right

was the diseased kidney. In another case the pains developed suddenly in the night, radiating to the bladder and urethra and accompanied with vomiting and chills. This pseudocolic recurred three or four times in two or three months, the patient having no pain in the intervals. One patient was a young man, apparently healthy until he noticed pollakiuria for two months, and then the pseudocolic above mentioned. Now, five months after nephrectomy, he seems in the best of health. In the case of a woman of 28 a similar sudden nocturnal pseudocolic was the very first sign of trouble.

THE IMPORTANCE OF A LOW PROTEIN DIET IN CHRONIC NEPHRITIS*

H. D. ARNOLD, M.D.
Assistant Visiting Physician, Boston City Hospital
BOSTON

In planning a diet for chronic nephritis three cardinal principles must determine our selection of food.

First, the amount of protein food must be limited. Since the power of the kidneys to eliminate nitrogenous material is impaired, the amount of such material ingested must be limited to what the kidneys can readily take care of. This necessitates the careful regulation and limitation of the amount of protein food ingested.

Second, a sufficient amount of nutrition must be furnished. Notwithstanding the limitation of protein food, it is essential that sufficient nutriment should be supplied for all needs of the organism. The diet must have a sufficient caloric value, and the loss from limitation of the protein food must be made up by a corresponding increase of the fats and carbohydrates. The caloric value of the diet is of less importance in the more acute stages of acute nephritis, or in acute exacerbations of chronic nephritis. Here, as in all acute diseases, no harm results if the diet for a number of days has a caloric value considerably less than is demanded by the needs of the organism. But in dealing with a chronic condition which may last for months or years, a sufficient number of calories must be furnished or else the body deteriorates from slow starvation.

Third, variety must be provided. No matter how satisfactory a given diet may be, it cannot be strictly maintained for a long time without the patient becoming so tired of it that he rebels. In a diet for a chronic disease, variety is absolutely essential. It must be provided wisely, or the patient will himself vary his diet, and will probably do so foolishly.

LIMITATIONS OF PROTEIN FOOD

It is safe to say that an average adult in health does not need more than 90 gm. of protein in his food daily. It is known from the investigations of Chittenden and others that a person leading an active life can get along and maintain a condition of health and strength over prolonged periods on about half that amount of protein.

For practical purposes I have taken 90 gm. of protein a day as the maximum for cases of chronic nephritis, above which it is unnecessary to go, and have taken 50 gm. as the minimum, below which it is undesirable to go. These are not absolute limits, for I have had patients in a quiescent stage of chronic interstitial nephritis who exceeded 90 gm. without apparent injury. On the other hand in some advanced cases the patients have done well on less than 50 gm. of protein in a day over long periods.

Practically, then, in the severer or advanced cases of chronic nephritis we limit the ingestion of protein to 50 gm. daily. In proportion as the case is less severe we allow more protein, taking 90 gm. as the maximum for the slight or inactive stages of the disease.

CALORIC VALUE OF THE DIET

As has been already stated, the diet in a chronic disease must provide a sufficient number of calories to meet the requirements of the system for heat, energy, etc. Roughly speaking, an average adult needs 2,000 calories in twenty-four hours if at rest (as a patient in bed), 2,500 calories for light activity, and 3,000 calories for moderate activity. Three thousand calories may be taken as the maximum, for in few cases of chronic nephritis are the patients warranted in doing an amount of work that requires more than that.

It will be found practically that individuals differ considerably in their demands in this respect. For example, I have had a number of patients who have been going about and leading a life of light activity, yet maintaining their weight, strength, and general condition of health on 1,500 to 2,000 calories. It is a mistake to force such patients against their inclination to take 2,500 calories or more, simply because it seems to be demanded on theoretical grounds. The maintenance of the weight, strength, and the general condition is a satisfactory practical test of the efficiency of the diet.

Loss of strength and energy and a marked feeling of lassitude are symptoms frequently complained of by these patients. This arises in part from insufficient nutrition, when the patient has a distaste for food, but also in many cases from the ingestion of too much protein in the food. For the waste products of protein metabolism, which the kidneys fail to eliminate, are largely the cause of these sensations and also of the extreme nervousness that is often present. It is extremely gratifying to see these symptoms diminish and disappear when, through the limitation of the protein food, the kidneys can remove the accumulations of waste material of this sort. The loss of appetite also seems to be caused by the excess of this waste material, for with its removal the appetite returns.

We often find patients going through cycles of alternating anorexia and good appetite. It is Nature's attempt to regulate the protein intake. When there is an excess of the waste products from protein food, anorexia ensues and the supply is cut down. When the excess has been removed, the appetite returns, often whetted by the resulting lack of nourishment. But unless the diet is properly proportioned, an excess of protein is quickly taken, and anorexia again ensues. This process is sometimes exaggerated through the belief on the part of the patient or physician that the feeling of weakness is to be combated by meat, eggs and milk, because of their reputed strength-giving properties.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

An increase in the amounts of these foods, relatively rich in protein, simply makes the condition worse instead of better, whereas most gratifying results are often obtained by diminishing the amount of protein ingested, provided sufficient energy is furnished by the other foodstuffs (fats and carbohydrates).

I may allude in passing to the danger in these cases of the fad of the free use of soured milk. If soured milk replaces other protein food, no harm is done. If, because the patient dislikes soured milk, less protein is taken, a distinct benefit may result. But I have seen distinct harm from the addition to a diet already rich in protein of a pint to a pint and a half of soured milk, representing an addition of 20 or 30 gm. of protein a day.

INADVISABILITY OF THE MILK DIET

It was formerly taught that the ideal diet for nephritis, chronic as well as acute, was a strictly milk diet. If other things were allowed in cases of chronic nephritis, it was not because they were considered more desirable. but because it was found practically that the patients would not adhere strictly to this diet for months at a time. Many physicians to-day are trying their best to keep patients with chronic nephritis as close as possible to a strict milk diet. Von Noorden was one of the first to point out a few years ago the fallacy of this line of treatment.

The objection to the exclusive milk diet lies in the fact that, if sufficient nutriment is to be supplied, an excess of protein must be given, whereas the protein should be diminished in order to spare the kidneys. This is easily demonstrated. Each 100 c.c. of milk contains approximately 4 gm. of protein and furnishes about 70 calories. Let us take 2,100 calories as a convenient number to represent the caloric need of an average patient. As each 100 c.c. furnishes 70 calories, it will require 30 times 100 or 3.000 c.c. to furnish 2,100 calories. In this there will be 30 times 4 gm. of protein, or 120 gm. It has been shown that 90 gm. is the maximum, above which we should not go; therefore, if enough milk is given to furnish a proper amount of nourishment, at least one-third more protein must be given than the maximum amount allowed under the most favorable conditions.

PROTEIN QUOTIENT

It is evident that an article of food is desirable in chronic nephritis according as it furnishes a large number of calories, and yet contains a small number of grams of protein, provided, of course, that it is easily digested and assimilated, and is acceptable to the patient.

I have found it convenient to classify the foods containing protein on this principle. I have used the word "protein quotient" to represent the number of calories furnished by a food for every gram of protein it contains. The protein quotient is the quotient obtained by dividing the calories furnished in a given amount by the number of grams of protein it contains. For example, since 100 c.c. of milk contain 4 gm. of protein and furnish 70 calories, therefore the protein quotient for milk is 70 divided by 4, or 17½, indicating that 17½ calories are obtained for every gram of protein in milk.

We may speak of the protein quotient of a diet. For example, if a diet contains only 50 gm. of protein yet furnishes 2,000 calories, its protein quotient is 40. Or if 90 gm. of protein is allowed for 2,000 calories the protein quotient would be 22 2/9. In chronic nephritis, then, the protein quotient will range from 22 to 40, and the more severe the case the higher should the protein quotient be.

Table 1 gives a list of the common articles of food arranged according to their protein quotients.

TABLE 1.—COMMON ARTICLES OF FOOD ARRANGED ACCORDING TO THEIR PROTEIN QUOTIENT

Cream (30%)	85.7	Fat ham	33⅓
Bacon	60.0	Mutton and pork	23⅓
Cake	58.0	Custard	20.0
Cream (20%)	57.0	Baked beans	18.0
Mashed potato	55.0	MILK	17½
Rice (boiled)	50.0	Soup (purée)	16⅔
Chocolate	46.0	Butter beans	16.0
Potato	45.0	Cheese (full cream)	16.0
Pudding (simple)	44.0	Lima beans	15.0
Zwieback	40.0	Green peas	14.0
Crackers	39.0	Buttermilk	13⅓
Shredded Wheat	35.0	"PROTEID PORTION"	12½
Parsnips	35.0	Fat meat	12.5
"CEREAL PORTION"	35.0	Egg	11.5
Green corn	33⅓	Scrambled egg	11.5
Cereal (cooked)	30.0	Fish chowder	11.0
Macaroni (cooked)	30.0	Oysters	8⅓
Bread	28.0	Lean meat	6.0
Gruel (milk)	25.0	Fish	6.0
Cocoa	25.0	Lobster	5.0
Beets, carrots	25.0	Beef juice	5.0
Onions, squash	25.0	White of egg	4.0
"Vegetables"	20.0

THE NEED OF DIET CHARTS OR TABLES

It is evident that, if these principles are to be applied in arranging the diet of a patient, certain data must be at hand in reference to the composition of different foods and their caloric value. Without these data, scientific regulation of the diet is impossible. This information may be obtained from Atwater and Bryant's tables,[1] or from tables now published in many books on dietetics and in some books on treatment. I presented to the profession a year ago a convenient diet chart,[2] which contained the statistics for the common articles of food, together with a brief summary of the principles of dietetics. The values given in this chart are approximate only, but are sufficiently accurate for practical use. They are taken as the basis of calculations in this paper. The chief value of the chart is its convenience. With such tables a diet containing the proper amount of protein and at the same time furnishing the desired number of calories can be constructed.

VARIETY, PROTEID PORTIONS, CEREAL PORTIONS

It was found that the third requirement was variety, in a diet that is to continue for a long period. The problem is to furnish variety and a sufficient amount of nutriment, and yet to regulate the amount of protein and prevent it from exceeding a given amount.

---

[1] The Chemical Composition of American Food Materials, Bul. 28, U. S. Dept. Agric. Off. Exper. Stations, Wash. (Revised edition).

[2] A Practical Diet Chart, Massachusetts Med. Soc., 1909; Boston Med. and Surg. Jour., Sept. 30, 1909, p. 457. These diet charts are now published by W. B. Saunders Co.

If the percentage of protein in different articles of food is known, it can easily be calculated what amount of each article will furnish a given quantity of protein. From our present point of view, these various amounts of the different articles may be regarded as equivalent one to another, and may be substituted for each other. I have designated these equivalent amounts of food as "portions." For example, milk contains 4 per cent. of protein, eggs 13 per cent., and meat 20 per cent. Therefore 100 gm. of milk would furnish 4 gm. of protein, the same amount of egg 13 gm., and of meat 20 gm. One egg weighs on the average 2 ounces, or 60 gm. Therefore it will contain approximately 8 gm. of protein. It would require 200 gm. (or c.c.) of milk to furnish 8 gm. of protein, but the same amount would be supplied by 40 gm. of meat. Therefore one egg may be regarded as equivalent to 200 c.c. of milk or 40 gm. of meat, and each of these amounts is one "portion." These albuminoid substances, known as proteids, and other similar articles which are relatively rich in protein are conveniently grouped together. Portions in this group are designated as "Proteid Portions," and the unit is 8 gm. of protein, the amount of protein contained in one egg. In a similar way bread contains on the average 9 per cent. of protein, boiled rice 2 per cent., and cooked cereals 2 per cent. It is found that an average slice of bread weighs about 40 gm. and contains about 4 gm. of protein. Two hundred gm. of boiled rice or cooked cereal would furnish the same amount. A number of the staple articles of food are grouped together on this basis of 4 gm. of protein to each portion, and for convenience these are called "Cereal Portions." Each cereal portion, containing 4 gm. of protein, contains half as much protein as the proteid portion, which has 8 gm.

TABLE 3.—PROTEID PORTIONS

Under this head are included the common articles of food that are relatively rich in protein. Each "portion" contains 8 grams of protein—the amount in one egg. Therefore, in calculating the amount of protein in a diet, one portion is equivalent to another. Variety may be secured by substituting one portion for another which has been ordered in a diet.

Each of the following amounts constitutes one proteid portion:

P.	F.	C.	Cal.		
8	5.5	....	80	Egg.	One.
8	8.0	8.0	140	Milk.	One "glass" (200 c.c.). (A tumbler or coffee cup 4/5 full.)
8	1.5	13.0	100	Buttermilk.	One-half pint. (A tumbler or coffee cup *full.*)
8 8	2.0 to 8.0	....	50 100	Meat or fish.	One and one-third oz. (40 grams). One oz. is the amount of meat in the lean part of a lamb chop; or 1 cubic inch of meat or fish. If steak or fish is 1/2 inch thick, surface would be 2x1 inches.
		Varies with amount of fat.			
8	10.0	1.0	120	Cheese.	One oz. (30 grams).
8	6.0	1.0	90	Scrambled egg, or omelette.	One and one-third tablespoons (80 grams).
8	3.0	8.0	90	Fish chowder.	One hundred grams (3 1/3 oz.).
8	5.0	13.0	130	Puree soup.	One-half pint.
8	7.0	16.0	160	Custard.	Four and one-half oz. (a small cup) (130 grams).
8	19.0	29.0	320	Ice cream	Five oz., a small cup, or rather large serving (160 grams).
8	2.0	3.5	65	Oysters.	Eight average-sized (each weighing 10 grams, or 1/3 oz.). (One oyster of this size contains 1 gm. protein.)
				Clams.	Same as oysters, according to size.
8	5.0	5.0	100	Average proteid portion (P. P.).	

TABLE 4.—CEREAL PORTIONS

The articles of food in this table are less rich in protein than those included under the head of proteid portions, but they are staple articles of food and a considerable part of the protein of the food is derived from them. The amount of protein in each cereal portion is 4 grams—the amount is a fairly thick slice of bread. Thus a cereal portion contains half as much protein as a proteid portion. Calculations and substitutes may be made in the same way as with proteid portions.

Each of the following amounts constitutes one cereal portion:

P.	F.	C.	Cal.				
4.0	0.5	24	115	Bread.	One and one-third oz. (40 grams). One slice of an average-sized loaf; 1 tea roll; ½ breakfast roll; 1 muffin.		
4.0	6.0	40	230	Cake.	Average piece 2 oz. (60 grams).		
4.5	4.0	28	165	Crackers.	One and one-third oz. (40 grams). (Weigh different kinds.)		
3.0	0.5	22	100	Shredded Wheat.	One biscuit.		
4.0	5.0	30	175	Pudding.	Simple puddings (bread, rice, Indian, tapioca, cornstarch), one serving, 3⅓ oz. (100 grams).		
4.0	10.0	38	250	Pie.	Average piece (100 grams).		
4.0	....	40	180	Potato.	Two moderate-sized,	200 grams,	1 potato = ½ C. P.
4.0	6.0	36	220	Mashed potato.	3 tablespoons.	200 grams.	1 tablespoon = ⅓ C. P.
4.0	....	12	60	Butter beans.	2 tablespoons.	40 grams.	1 tablespoon = ½ C. P.
4.0	....	11	60	Lima beans.	2 tablespoons.	50 grams.	1 tablespoon = ½ C. P.
4.0	....	10	60	Peas.	2 tablespoons.	60 grams.	1 tablespoon = ½ C. P.
4.0	....	27	125	Green corn.	3 tablespoons.	140 grams.	1 tablespoon = ⅓ C. P.
4.0	1.0	24	120	Cereal (cooked).	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	1.0	33	160	Corn Flakes, etc. (dry cereals).	8 tablespoons.	40 grams.	1 tablespoon = ⅛ C. P.
4.0	....	48	200	Rice (boiled).	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	2.0	21	120	Macaroni.	4 tablespoons.	140 grams.	1 tablespoon = ¼ C. P.
4.0	2.0	21	120	Vermicelli.	4 tablespoons.	140 grams.	1 tablespoon = ¼ C. P.
4.0	....	30	140	Parsnips.	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	....	20	100	Carrots.	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	....	20	100	Squash.	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	....	20	100	Turnips.	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	....	20	100	Onions.	4 tablespoons.	200 grams.	1 tablespoon = ¼ C. P.
4.0	1.0	30	140	Average cereal portion (C. P.).			

Table 3 gives a list of proteid portions, and Table 4 gives a list of cereal portions. In these two tables are included all the more common articles of a mixed diet, and from them sufficient variety may be obtained to satisfy any reasonable person.

The regulation of the amount of protein ingested is easy by means of these portions. We can order a certain number of proteid portions (P.P.) and a certain number of cereal portions (C.P.) and know with sufficient accuracy just how much protein the patient gets, although he may be given free choice of all the articles in these lists. For example, if it is desired to give the patient 60 gm. of protein in a day, 4 P.P. (4×8=32) and 7 C.P. ($7\times4=28$) can be ordered; or 5 P.P. ($5\times8=40$) and 5 C.P. ($5\times4=20$). If the patient is ordered 5 P.P., he might take 2 eggs, one glass of milk, and 2 lamb chops; or one egg, one portion (40 gm.) of fish, 80 gm. of meat, and a cup of custard; or any other combination to make up 5 P.P.; yet from these 5 P.P. he will always get 40 gm. of protein. From the 5 C.P. he will get 20 gm., and the total will always be 60 gm., whatever the combination.

Variety and the regulation of the amount of protein, having thus been provided for, it must next be considered how this scheme affects the problem of the amount of nutrition—the total calories for the day. For, although each portion contains the same amount of protein, the number of calories varies considerably. For example, 1 P.P. of lean meat furnishes only 50 calories, while 1 P.P. of ice-cream furnishes 320 calories; or 1 C.P. of butter beans furnishes 60 calories, while 1 C.P. of cake gives 230 calories. These seem wide variations, but when a person is changing the diet rather frequently he comes pretty near the average figures given in the tables. Sufficient accuracy will therefore be attained by counting each proteid portion as 100 calories and each cereal portion as 140 calories.

THE METHOD OF PLANNING A DIET

The number of grams of protein that the patient should have must first be determined according to the severity of the case. Then the number of calories the diet should furnish must be decided. This is determined by a consideration of the normal weight of the patient and the amount of his activity.

An adult requires in twenty-four hours:

At rest	14-16 calories per pound of normal weight.
At light work	16-18 calories per pound of normal weight.
At moderate work	18-20 calories per pound of normal weight.

Roughly stated, an average-sized man requires:

At rest	2,000 calories in 24 hours.
At light work	2,500 calories in 24 hours.
At moderate work	3,000 calories in 24 hours.

Let us suppose, for example, that it is desired to prescribe a diet which contains 70 gm. of protein and furnishes 2,000 calories. It is desirable to prescribe a certain amount of cream in such a diet, both because it is an acceptable article of food and because of its high caloric value and relatively low amount of protein.

	P.	F.	C.	Cal.
Cream, 20 per cent., 1 oz.	1	6	1	60.
Cream, 30 per cent., 1 oz.	1	9	1	90.

Each ounce of cream contains 1 gm. of protein. A patient can readily take from 2 to 6 or 8 ounces of cream daily.

In planning a diet for a given number of grams of protein, the first number lower that is divisible by four is selected. This number of grams, being a multiple of four, can be provided for from the proteid portions and cereal portions. The number of grams above this is furnished by cream, each ounce of cream furnishing 1 gm. All the protein has now been provided for and no more can be added. The number of calories which have already been furnished are calculated and then the balance is provided for by articles which do not contain protein, such as butter, sugar, fruit, etc. These articles and their composition and caloric values are given in Table 2.

For example, it is desired to get 2,000 calories from a diet containing only 70 gm. of protein. The first number below 70 that is divisible by 4 is 68. Therefore 2 ounces of cream are ordered and the remaining 68 gm. are divided among the proteid and the cereal portions. If 5 P.P. is tried, that furnishes 5 times 8 or 40 gm. of protein, and there are 28 gm. left, which would be provided for by 7 C.P. Now 5 P.P. furnish on the average 500 calories, 7 C.P. furnish 980 calories, and 2 ounces of 20 per cent. cream furnish 120 calories. This provides for 1,600 calories. Since 2,000 calories are wanted and no more protein can be given, 400 calories must be obtained from non-protein foods. One ounce of butter would furnish 240 calories, 250 gm. (half a pound) of sweet fruit would give 100 calories, and 3 teaspoonfuls of sugar would give 75 calories. The total is 415 calories, or 15 calories more than is needed. It is not difficult to calculate such a diet.

This diet is tabulated in Table 5:

TABLE 5.—DIET FURNISHING 2,000 CALORIES WITH 70 GRAMS PROTEIN

	P	F.	C.	Cal.
5 P.P.	40	25	25	500
7 C.P.	28	7	210	980
Cream, 20%, 2 oz.	2	12	2	120
Butter, 1 oz.	..	27	...	240
Sweet fruits, 250 gm.	..	..	25	100
Sugar, 3 teaspoonfuls	..	..	18	75
Total	70	71	280	2015

The diet may be varied further by the addition of any of the so-called "fodder-vegetables," which include asparagus, string beans, Brussels sprouts, cabbage, cauliflower, celery, cucumbers, greens, lettuce, pumpkin, radish, rhubarb, spinach and tomatoes. These do not in themselves furnish enough protein or nourishment to count. They are, however, acceptable to the taste, they add to the volume of the meal, and they offer a ready method of introducing butter or oil in the diet. They may be taken in such amounts and variety as are desired, provided they are easily digested.

This diet may be reduced to ordinary terms for the patient as follows:

Breakfast.—Fruit, 125 gm. (one-half of a large orange). Cereal. 4 tablespoons (1 c.p.), with 1½ ounces of cream and 1 teaspoonful of sugar. One egg (1 p.p.) on 1 slice of toast (1 c.p.) with 1 pat (⅓ oz.) butter. Coffee, with ½ ounce cream and 1 teaspoonful sugar.

Lunch.—Scrambled egg, 80 gm., 1⅓ tablespoons (1 p.p.). Toast, 1 slice (1c.p.) with 1 pat butter. Cake, 60 gm., average piece (1 c.p.). Fruit, 125 gm.

Dinner.—Oysters, 4 average-sized (½ p.p.). Purée soup, 4 ounces (½ p.p.). Fish, 40 gm. (1 p.p.). Meat, 40 gm. (1 p.p.). Bread, 1 slice (1 c.p.), butter, 1 pat. Potato, 1 moderate-sized (½ c.p.). Boiled rice, 2 tablespoons (½ c.p.). Spinach (or other fodder vegetables). Pudding, 100 gm., 1 serving (1 c.p.). Coffee, demi-tasse, with 1 teaspoonful of sugar.

With such a diet planned, the patient is instructed that wherever a proteid portion or a cereal portion is indicated, any other equivalent portion from the list may be substituted. Moreover, if at one meal he does not care for the full allowance, any article omitted or its equivalent may be taken at another meal. The patient may, if he desires, take more fruit, butter, sugar, or other non-protein food than is ordered.

Such a menu gives a patient a diet that is sufficient in amount and nutritive value, is satisfactory in variety to most people, is easy to obtain at an ordinary home table or at a hotel, and can be varied by the patient to suit his taste: and yet with all the changes the patient is getting a well-balanced ration and his protein intake is strictly regulated.

I find that patients are able to understand these regulations without much difficulty, although the patient should be kept under rather close supervision until the ideas are thoroughly understood. Later the patient should make a report at stated intervals as to just what he has taken in twenty-four hours. In this way a case may be followed and controlled indefinitely.

Where accuracy is important the food should be actually weighed. It is a good plan to do this at the start in any important case. After weighing the different kinds of food for a time the portions can be estimated with sufficient accuracy by the eye. For the purpose of weighing food at the table I have found the food scales designed by Dr. Hart extremely satisfactory.[3]

RESULTS

What can be accomplished by such regulation of the diet?

Much will depend on the stage of advancement of the disease and on its activity. The treatment is prophylactic and palliative rather than curative. Naturally the best results are obtained in cases in which the functions of the kidneys are but little impaired, in the early or inactive stages of the disease. But surprisingly good results have been obtained in some cases of cardiorenal disease, so advanced that we should ordinarily despair of helping them.

When the protein metabolism can be adjusted relief from those symptoms which are due to failure to eliminate these waste products is obtained, and a condition of relative health is restored. The relief from nervous symptoms, anorexia, and the feeling of lassitude or fatigue has already been mentioned. Perhaps the most gratifying result, however, is the lowering of blood-pressure and the consequent relief of the burden thrown on the heart. It would appear that the increased blood-pressure in case of chronic nephritis is due, in part at least, to the excess of these waste products in the body. Such a reduction of blood-pressure cannot be secured in every case, but a gratifying reduction occurs in a large majority, and a surprising drop in many. Blood-pressures ranging from 200 to 180 mm. are commonly reduced below 160, not infrequently to 150 or 140.

One of my patients over 60 years old, starting with a blood-pressure of 190, finally reached and maintained for months a pressure ranging from 120 to 130. He enjoyed better health and strength than at any time since the symptoms arose two years before, but he died recently from an intercurrent disease, being unable to resist successfully an acute infection which resulted in pleurisy and pericarditis. I am confident that his life by regulation of the diet was prolonged fully two years longer than it would have been otherwise. I can see no reason why he should not have lived for an indefinite period longer but for this intercurrent affection.

Another patient was taken in charge a year and a half ago, after the second severe attack of uremic convulsions occurring within three months. He has been free from uremic attacks since then; he is in better health than for a number of years, and his blood-pressure for the past year has shown an average of 160, although it was 210 when treatment began.

In another case of advanced interstitial nephritis with failing cardiac compensation the blood-pressure was reduced from 260 to 180, although the patient had had symptoms for two years and marked symptoms for several months. In this case, however, the improvement lasted but two months, although during that time the patient was practically free from symptoms. Then the former symptoms recurred, with an increase of blood-pressure, so that in two months more it had again reached 260. The patient lived only about two months after that. Surely this was a very advanced case, yet great relief ensued for a time.

Such results cannot be secured in all cases, of course; nevertheless, they are exceptional rather in the degree of reduction of blood-pressure than in the fact that a satisfactory result was obtained. I have had a good result now in so many cases in which I hardly dared hope for it, that I am beginning to predict relief in almost every case. Contrast such results with the transient and unsatisfactory results of drug treatment, and I think you will agree that it is well worth while to take the moderate amount of trouble involved in the proper regulation of the diet.

The stumbling-block in the past has not been the absence of sufficient knowledge, for the scientific laboratory workers have known the underlying facts for years, but the difficulty of getting that knowledge into a form simple enough to enable the physician to apply it in every-day practice. This difficulty is overcome, at least in large measure, by the charts and tables here mentioned.

427 Beacon Street.

ABSTRACT OF DISCUSSION

DR. G. C. SMITH, Boston: I have been interested during the past fifteen years in dietetics in chronic diseases, and the best methods of dealing with chronic affections. There are so few remedies in the way of drugs that can be continued with benefit for a long time, that it is necessary to get at these troubles in some other way, and the dietetic way seems to be the one indicated. The first instruction in New England given on the subject of dietetics has been given by Dr. Arnold. It is really a misfortune that every institution teaching medicine in this country does not have a definite chair of dietetics. It seems to me that this is too large a subject for a man who is teaching another subject to give instruction on. For the past two or three years, however, there has been an improvement in the manner in which the young physician in New England handles the chronic cases, dietetically speaking. Our experience has been somewhat different from Dr. Arnold's in some respects. The question of calories which enters into any diet can be modified very much, as explained by Dr. Arnold in his tables. In other words, in the cases that are primarily renal, the patients as a rule are very thin, usually cold and anemic. In such patients, the carbohydrates and fats must predominate in the diet. On the other hand, in the cardiorenal cases we often find the reverse. In these cases frequently the cardiac part is primary and the interstitial changes or process in the liver, the kidneys and elsewhere are secondary and consequent upon the prolonged congestion of these organs. Such a prolonged congestion, with the long duration of the disease, produces changes in metabolism which weaken the patient, making him take much less nourishment because he suffers with indigestion. The nourishment too may be of the wrong kind, *e. g.:* One may cut out the proteid and increase the "pap," and especially the sweets and bread with their high percentage of starches. By doing this and adding cream and butter the calories are much increased. Such patients are unable to take much exercise because of the cardiorenal disease; therefore, they remain in the house and at rest. A reduction in the number of calories in such cases should be made by reducing the amount of fat and carbohydrates Then the question of the proteid element comes up There is no doubt in this class of cases but that the proteid element must be higher than seventy grams, one cannot produce an improvement in metabolism without more proteid, hence we must give it to furnish the best nutrition for the cells of the body Consequently in all these cardiorenal cases it will be found advisable to raise the amount of proteids higher than physicians as a rule recommend This may be considered a little off from the subject of the paper, but it is such a common thing to find the renal and cardiac cases mixed that it is well to consider them

---

[3] Hart, T. S.: A New Food Scale, THE JOURNAL A. M. A., Aug. 7, 1909, p. 457

Dr Philip S Roy, Washington, D C · I have used Dr Arnold's charts regularly As to the question of fats and carbohydrates overloading the system and the metabolism becoming deranged as a consequence thereof, as mentioned by Dr Smith, I have not found that the case if Dr Arnold's plan be followed When one wishes to lessen the number of carbohydrate calories, he can replace these calories with fat Three pints of milk with a pint of cream and one ounce of butter equals about 2,000 calories This will give all the energy needed I am in accord with the statement that the proteids in disease of the kidney should not be above 50 grams daily

Dr H D Arnold, Boston I am glad that Dr. Smith mentioned the cardiorenal cases in which the cardiac end predominates The problem here is somewhat different, in that the power of the kidneys to eliminate nitrogenous material is less seriously impaired Greater liberality in the use of protein food may be allowed, yet even in these cases there is no necessity for large amounts I think that 50 grams of protein are enough for the purposes of tissue building, including the heart It is of great importance that there should be an abundant amount of nutrition—a sufficiently high caloric value to the diet—but beyond the amount of protein needed for tissue building, this nutriment is just as well, if not better, derived from the other foodstuffs Often, however, our plan must be modified because of questions of digestion and assimilation Some people cannot digest fats well, and others have difficulty with the carbohydrates I would not be understood as maintaining that we must always give the number of calories which are indicated by theoretical calculations Often we find a patient will maintain weight and strength, and may even gain, on 1 500 calories when 2,000 or more are demanded theoretically If such is the case it is a mistake to force the patient to take the larger amount

The only credit I feel that I am entitled to in this work is in getting our knowledge in dietetics into a simple, practical form for application in ordinary practice There is nothing in it that is new or that has not been utilized by the laboratory workers in metabolism experiments for years But the data have been too complicated for use in ordinary cases and have not been easily available If we can apply these principles to ordinary patients we shall plan diets with far more intelligence than we have done in the past

Health and Sanitation in Cuba—Reporting the result of an inspection trip over the Island of Cuba (*Sanidad y Beneficencia*, April, 1910, p 305), Dr Manuel Varona Suarez Secretary of Health and Charities, says that there did not exist a single case of quarantinable disease with the exception of leprosy, and that his country was on a level with the healthiest communities in the world He also asserts that should such a disease enter the country the efficient sanitary organization of the island would be able to ward off the threatening danger He feels that the national health department is efficient but regrets that he cannot say as much for the sanitary service in the municipalities, for he found with a few exceptions that vaccination was neglected, that the public slaughter houses were in a shameful condition, and that the cemeteries were almost as much neglected Two great obstacles to efficient sanitation were lack of water supplies and sewerage systems His inspection convinced him of the urgent necessity of establishing dispensaries and sanatoriums at appropriate sites in the various provinces and of founding hospitals and special wards for the care of the large consumptive population which lacks resources to protect itself against the disease and which constitutes the chief factor in its propagation

APPENDICITIS IN CHILDHOOD

WITH A REPORT OF 500 CASES *

H. C DEAVER, M D.
Professor of Surgery, Woman's Medical College of Pennsylvania;
Visiting Surgeon to Episcopal, St Agnes' and Stetson Hospitals, and Children's Hospital of the Mary J.
Drexel Home
PHILADELPHIA

This paper is based on an analysis of 500 cases in which I operated at the Children's Hospital of the Mary J Drexel Home, and on a review of the more recent literature.

Appendicitis in childhood, characterized as it is by subtle and insidious onset, rapid progress and obscurity of symptoms, is a disease of the most profound importance, and it well merits more attention and study than has hitherto been bestowed on it.

The earliest case of appendicitis was reported by Dixon,[1] and occurred in a baby, aged 24 days, which was premature at the eighth month. The appendix was gangrenous and formed, with part of the cecum and ileum, the contents of a sac of a strangulated inguinal hernia Since the appendix was adherent to the sac, Dixon held it responsible for the descent of the ileum and cecum A very similar case is reported by Lilienthal[2] Other cases of infantile appendicitis are reported by Bamberg,[3] in a child, aged 5 weeks; by Dennis and Goyens, in two infants, aged 6 weeks, and by Blumer and Shaw, in one, aged 7 weeks. Berkholz[4] reports four cases in infants, aged 12, 15, 17 and 19 months, respectively, while Schellong[5] met a case in an infant, aged 21 months Alsberg[6] gives as his youngest patient a baby, aged 6 months, while Springer[7] has seen none younger than 3 years. My youngest patient was 21 months old. Mayet (cited by Springer) collected reports of nine cases of appendicitis in infants. In 1,000 cases McCosh[8] found 1 7 per cent. in children up to 5 years of age. My statistics, however, place the frequency in the first five years at about 8 per cent. This frequency in the first five years of life will probably be diminished under more refined diagnoses Churchmann[9] thinks that infantile appendicitis deserves separate consideration from that occurring later in childhood, stating, with much truth, that the surgical problem of infantile appendicitis is that of diagnosis, and that the difficulty of diagnosis keeps up the mortality. So, also, von Bramann[10] asserts that the danger of appendicitis is greater in the first years of life than later, and gives a 50 per cent. mortality in all infants under 5 years of age that were present in a series of 117 cases in children In those from 6 to 10 years of age, inclusive, the frequency jumps from 8 per cent to 36 per cent., finally reaching 56 per cent. in those between the ages of 11 and 15 years.

As to sex, males predominate Riedel[11] found that of 1,532 patients 955 were males and 577 females. My series showed 315 males and 185 females.

The microscopic pathology of acute appendicitis has been carefully studied by Alsberg,[6] who emphasizes the importance of fixing the appendix in 0.8 per cent. formaldehyd solution immediately after its severance from the cecum. The most important changes, of course, are in the mucosa, but the other coats act in sympathy, as the inflammation increases in intensity from the center toward the periphery. In the mucosa the epithelium is desquamated, often eroded and extensively destroyed, and hemorrhages are frequent. The solitary lymph-nodules are enlarged, thickened and studded with polymorphonuclear eosinophils. Alsberg warns against mistaking the exceptionally well-developed nodules of children beyond 2 years of age, especially when cut oblique, for inflammatory changes. The submucosa and sometimes the muscular coat is edematous and the blood and lymph-vessels distended and choked with leukocytes. The serosa is congested and often covered with white fibrin. Ulceration may extend through to the serosa, producing appendicitis granulosa of Riedel, which involves, by predilection, the hip.

In chronic appendicitis also the principal changes are found in the mucosa, in which the epithelium and mucous glands are destroyed and the lymph-nodules atrophied, while contractions may obliterate the entire length of the lumen, or only one part of it. Stenosis near the base of the appendix leads to the formation of hydrops or empyema, and, if near the tip, produces a globular swelling, which, however, causes little or no danger. Adhesions, more or less extensive, may be connected with other organs more remote from the ileocecal region than in adults, because of the greater length of the appendix in children, which compared to that of the large intestine, is, according to Ribbert, 1.1 in new-born children and 1.2 in adults. This circumstance accounts for many mistaken diagnoses, Schellong[5] reporting a case in which the appendix ran transversely behind the bladder to the left and set up a left-sided appendicitis. Riedel[11] states that strictures are relatively rare in children, because a long time is required for their formation. He places their frequency in adults at 26.5 per cent. and in children at 8.7 per cent. Fecal concretions, on the other hand, are relatively common, Springer[7] having found them in 59 per cent. of acute cases and in 20 per cent. of chronic. They are even more frequent than in adults, in the proportion, according to Riedel, of 39 per cent. in children and 27.7 per cent. in adults. The same author states that the worst attacks are associated with suppurating fecal concretions. It is interesting to observe that Low found meconium in the appendix of a 5-month fetus.

Often, the regional lymph-nodules are swollen, indurated and inflamed, and Comby[12] regards them as "witnesses of infectious processes of which appendicitis is the stage." Churchmann[9] states that the pathology of appendicitis in children is distinguished from that of adult life by the tendency to early perforation and the frequency of spreading peritonitis, and Sloan[13] observes that the undeveloped omentum affords less protection against rapidly spreading peritonitis.

The predisposing causes of appendicitis are said to be infectious disease, family disposition, dental caries and mechanical irritation. Of the infectious and contagious diseases, enteric fever, scarlatina, influenza, mumps, pertussis and chicken-pox, have been mentioned. Enteric fever and intestinal catarrh certainly produce congestion of the appendix, which, with superficial loss of epithelium, may prepare the way for infection of the deeper layers. As to scarlatina, Springer states that Ganghofer, in twenty years' experience with scarlet fever, did not observe acute appendicitis in a single instance. Epidemics of influenza often leave in their wake severe acute attacks of appendicitis; certainly, influenza readily affects lymphoid organs. Chicken-pox was more than likely the cause of appendicitis in Schellong's case. The etiologic status of nasopharyngeal troubles, tonsillitis, adenoids, cervical adenopathies and otitis media, is problematic, as the path by which the exciting cause of these conditions reaches the appendix is somewhat obscure, unless it is assumed to be hematogenous. Sloan[13] states that the period of greatest development and activity of the lymphoid tissues corresponds to the period of greatest incidence of appendicitis. Family disposition is emphasized by the French, and may be accounted for by the irregular mode of life among poor families, so that neglect, improper feeding and insufficient medical attention may bring about appendicitis as well in one child of a family as in another.

Jackson[14] presents eleven arguments why dental caries should cause appendicitis, the most striking of which are that infants suffer rarely and that the civilized have both dental caries and appendicitis, while the uncivilized have good teeth, and no appendicitis. Teeth, examined by Alsberg in nine children with appendicitis, were carious, and partly absent in six and normal in three. Mechanical irritation may be caused by errors of diet and foreign bodies. Errors of diet, though undoubtedly responsible for recurrences in adults, are probably only remotely connected with acute appendicitis. Springer has noticed no increase in the frequency of acute appendicitis when the fruit season is at its height. Fecal concretions and other foreign bodies may irritate the appendix enough to permit the entrance of bacteria through epithelial abrasions, but, on the contrary, they may lie dormant for a long time and, not rarely, throughout life. Alsberg found two bits of enamel in an acutely inflamed appendix. To intestinal worms, by their frequency in childhood, might be ascribed a causative rôle. In large numbers (as, for example, 80 oxyuris in an appendix extirpated by Hippius-Levinsohn, cited by Springer) they could block the lumen of the appendix, cause colic, and injure the mucosa superficially by trauma and by the elaboration of toxins. The exciting cause of appendicitis is, of course, bacterial, and usually *Bacillus coli communis,* which is ever alert to invade the walls of the appendix through a *locus minoris resistentiæ* offered by any of the predisposing causes. Other pyogenic organisms may act alone or in conjunction with *B. coli.*

The symptoms of acute appendicitis in infants are unquestionably scanty, irregular and misleading, and it undoubtedly follows that infantile appendicitis is more frequent than is generally believed, or than statistics show. Thus, at autopsy on a 2-weeks-old infant that died of severe acute enteritis, Deiss (cited by Soltmann) found acute appendicitis with serofibrinous peritonitis, without having produced any clinical symptoms, and concludes from this that such findings in infants, even when less severe, are frequent. So, too, Churchmann states that appendicitis of the severest type may exist without one of the classic symptoms, and that even a general peritonitis may develop under observation.

In older children, on the contrary, symptoms reach the other extreme, and acute attacks, even more regularly than in adults, occur suddenly and with very stormy symptoms. There are severe pains which localize about the navel, shortly followed by vomiting, rigidity, more or less extensive, and abdominal distention. The temperature is usually higher than in adults and the pulse more frequent. On the whole, these children give the impression of being seriously ill, lying on their backs with legs drawn up, or curled up on their side, writhing from pain. It must be remembered that the child may be mentally incapable of accurately locating the pain, often pointing to various parts of the abdomen as the place of greatest intensity. Voluntary rigidity is common in children, owing to fear. Hyperpyrexia is an attribute of childhood, and the rapid pulse is due in part to the hyperpyrexia, and in part to the restlessness of the child. Thus, it is evident that the reaction of the whole organism is more active in childhood than later.

In chronic appendicitis the whole organism may be affected by the presence of a chronic focus of infection. The troubles are chiefly digestive. The appetite is capricious and varies from day to day. The tongue is coated and the breath bad. Digestion is slow and dyspepsia marked by flatulence and epigastric swelling after meals. Constipation is habitual and obstinate. Such disturbance may interfere with nutrition even to the extent of emaciation. The face may be thin, pale and sallow, and there may be black circles about the eyes. On the other hand, sufferers from chronic appendicitis may have rosy cheeks and a generally healthy condition. There may be circulatory disturbances, as pallor and blushing of the face, cold hands and feet, and cardiac palpitation and dyspnea on exertion. Secondary anemia, with a murmur at the base of the heart may exist, and fainting may occur. Appendiceal neurasthenia may render children dull and silent and "friends of solitude and repose."

The diagnosis of appendicitis in infancy and childhood should be made easy by the epigram: "All cases of abdominal trouble in children are appendicitis until proved otherwise." With this proviso, there should follow a systematic examination of all organs. In infancy it is unquestionably difficult, yet usually capable of being established. In this solution it must be borne in mind that the younger the child, the more deeply the appendix lies in the pelvis, owing, according to Selter, to the deep position of the cecum in the pelvic fossa. Hence, it is conceivable that bladder symptoms may monopolize the attention of the examiner, there being cloudy urine from edema of the bladder, tenesmus, and even retention from direct irritation of the bladder wall. Many cases have been reported in which urinary symptoms predominated. Churchmann writes that all urinary symptoms in childhood suggest the possibility of appendicitis. For the same reason pelvic abscesses are common, and may simulate abscesses from other causes, so that the same author states that in infants with apparent hip-joint disease, particularly if the thigh be flexed, the same possibility should be kept in mind. It is obvious then that every possible means of reaching in and about the right iliac region must be employed. The simple procedure of catheterizing the bladder may go a long way toward clearing up a doubtful case, and evacuating the phantom pelvic abscess.

By far one of the most important procedures in children is rectal palpation, and this must never be neglected. Churchman states that palpable resistance on the right side by rectal examination is one of the most frequent findings, and Selter calls it absolutely constant. In Schellong's case, the symptoms were characteristic of rectal abscess, including fever, rectal tenesmus and frequent small slimy stools. Rectal examination revealed within half a finger's length an abscess which protruded from above and to the right toward the rectum. Doubtless this rectal palpation has been the sole element of correct diagnosis in numerous cases, including two of my own. Tenderness at McBurney's point, when present, is almost pathognomonic, but the wandering appendices of childhood may carry their tenderness elsewhere. Thus, tenderness may be greater on the left side than on the right, as when the appendix is in the pelvis. Other signs, more applicable to older children, are hyperesthesia of the skin, and the fact that sudden removal of the palpating finger-tips from the point of greatest tenderness is more painful than the finger-tips themselves. Carstens[15] recommends palpatory percussion. Flexion of the right thigh on the abdomen is likewise very suggestive. In chronic appendicitis the organ is more often palpable than in adults, and an analytic study of the symptoms, together with localization of the tenderness at or near McBurney's point, usually establishes the diagnosis.

An appreciation of the difficulties of differential diagnosis may be had only by scanning the various and varying cases reported in the literature. Affections of the thoracic, abdominal and pelvic viscera, as well as of near-by joints, may enviously mimic the peculiar little ways of the appendix. The old question of pneumonia or appendicitis must be cautiously considered, particularly right-sided central pneumonia with but few physical signs. At the onset of right-sided croupous or central pneumonia, pain is often referred to the abdomen, and incriminates the appendix. This abdominal hyperesthesia may disappear by firm manual pressure, and the abdominal walls relax between respirations, which are very rapid. There may be herpes and cyanosis of the lips. In puzzling cases, careful observation usually clears the diagnosis within twenty-four hours. Cholelithiasis is rare in childhood, yet Alsberg mentions a typical gall-stone attack in a 3-year-old child, with the passage of gall-stones. Julien[16] reports a case of perforative appendicitis with retrocecal abscess, which was diagnosed as hepatic colic. Pancreatitis, renal colic, and movable kidney are rare in childhood. Intestinal catarrh, especially when accompanied by colic, may seriously cloud the diagnosis because of pain, vomiting, increased abdominal tension, fever and rapid pulse.

Of the intestinal obstructions, intussusception may be distinguished by the tympanites, by paroxysmal pain, by the discharge of bloody mucus from the anus, and by the late appearance of inflammatory peritoneal reaction, although if seen for the first time in the stage of general peritonitis, differentiation from appendiceal peritonitis is impossible, and in such cases operation is the safest procedure. Intussusception is of importance because of its frequency in childhood. The dense, sausage-shaped tumor, which shifts and varies in size, even to the extent of being reached by rectal palpation, as the intussuscipiens advances, may be helpful in diagnosis. Springer was led to the erroneous diagnosis of perforative appendicitis with peritonitis in a case which autopsy showed to be volvulus, caused by a lymphangioma in the mesentery of the small intestine. This case suggests the possibility of a congenital mesenteric cyst, such as I recently[17] reported, likewise being confused with acute appendicitis. In one of my cases, a right ovarian cyst twisted on its pedicle, in a girl aged 12, simulated acute appendicitis. In girls, salpingitis and gonococcic peritonitis must be considered, and the presence of vaginal discharge or vulvovaginitis will be helpful, as well as rectal examination. Tuberculous peritonitis was mimicked by a case of appendicitis reported by Rubritius and Hermann (cited by Springer) from von Jaksch's clinic. Acute cystitis in small children, caused by the colon bacillus, gives rise to fever, pains about the navel and vomiting. Here urinalysis, which often must be made repeatedly, suggests the diagnosis. Chronic appendicitis, by causing adhesions to the bladder, may be confused with cystitis. Lumbar abscess, such as may accompany Pott's disease, was diagnosed by Julien[16] in Case 4 of his series, a girl aged 4 with appendiceal abscess, which was evacuated by lumbar incision. In right-sided hip-joint disease there is absence of inflammatory peritoneal reaction, presence of muscular contracture, and the demonstration of foci of diseased bone. Churchmann reports cases which simulated this as well as vesical calculus, intestinal obstruction, associated with roundworms, and even cerebrospinal meningitis. Diagnosis in cases treated medically must always be uncertain.

[16] Julien: Echo méd du Nord, 1907, xi, 859

The prognosis of acute appendicitis is favorable, if the case is received early, and if the appendix is removed early. If the patient is operated on within the first twenty-four hours, the mortality is practically nil. Beyond this time, in suppurating cases, the mortality rapidly rises and after the third or fourth day is nearly as unfavorable as it was favorable in the early stage. With the flight of time, thinner grows the hair that suspends the sword of Damocles. Moreover, the danger of acute appendicitis is greater in the first two years of life than later. In chronic appendicitis, while there is no immediate danger, yet an acute attack with perforative peritonitis is always to be feared. In fact, as Alsberg expresses it, "A person who has once recovered from an attack of appendicitis sits on a barrel of gunpowder."

As regards the value of the leukocyte count, I agree with Soltmann that the greater the leukocytosis, and the larger the relative percentage of polymorphonuclears, provided the temperature and the pulse are proportionate and not high, the more favorable the prognosis; while the lower the leukocytosis, with lower temperature and more frequent pulse, the more unfavorable and severe the course. He thinks that leukocytes here play a rôle similar to that which they play in the autolysis of the lungs in pneumonia, where a proteolytic ferment exerts a digestive action on the exudate.

The ideal treatment will maintain the mortality at nil. This ideal will be attained only when all patients are operated on early. That early operation is the normal course to pursue is now conceded by the world's surgeons. It is true that more early cases are received than formerly. That is why the mortality is decreasing as the years roll on. But the desideratum is that all patients be received early. I believe that the fault is not so much with the medical profession as with the ignorance and prejudice of parents. How many patients do we receive, sick from three to seven days, with pus-laden abdomens, and the parents beseeching us to operate!

The time to operate, then, is before the storm breaks, and while the noon-day quiet holds the hill. Twenty-eight of the appendices in my series were ballooned with pus, and on the point of exploding, when removed. Such an organ, like Vesuvius, threatens the entire peritoneal cavity. A unique feature of appendicitis, up to and during this stage, is that the entire area of acute inflammation and phlegmon can be removed with nothing but benefit to the patient. Where else in the body is such a thing possible? Can a digit, the seat of a felon, be amputated with propriety? Can a pyosalpinx be removed with the same disregard for the value of the organ? Can even a surface phlegmon, as a carbuncle, be removed *in toto* in a similarly satisfactory manner? Inconceivable! Here, then, is an organ which, together with the disease that has attacked it, can be ablated without depriving the patient of an organ or tissue of any recognized value.

In cases in which there is a localizing abscess, with diffuse peritonitis, general abdominal tenderness, with more or less distention and bilateral rigidity, moderately high temperature and rapid pulse, with a low leukocyte count and a large percentage of polymorphonuclears, it is best to defer operation. With the ebbing of the tide, there is often revealed a mass stranded on the pelvic shelf, an indication that the omentum and coils of intestine have had time to assemble and form a barrier to the pus. With the evacuation of the abscess, recovery is practically assured. In twenty of my cases I waited from two to twelve days before operating.

Such cases are managed very much the same as cases of acute pyosalpinx. Rest in bed, ice-packs to the abdomen, the Fowler position, gastric lavage, rectal instillations of saline solution and no water, no nourishment by mouth, no purgatives, no opium.

Opium clouds the symptoms and makes the diagnosis more difficult. By favoring tympanites, it interferes with palpation and percussion, and, by diminishing or removing pain, it makes severe cases assume a more benign aspect. It also retards the defensive activities of the leukocytes. Purgatives must be withheld absolutely. This statement cannot be made too strong. The majority of badly progressing cases of appendicitis have been treated with purgatives and the most unfavorable turn often dates directly from the time of their administration. Cases have been reported in which purgatives have produced perforation. As one writer expresses it, "First purgatives, then death." Cathartics must never be given unless it is absolutely certain that appendicitis is absent. By increasing peristalsis, they interfere with the localizing process, and in the presence of perforation, increase fecal extravasation. If spontaneous defecation does not occur after the most acute symptoms have subsided, it may be assisted by small, lightly injected enemas of soap suds or oil, or by suppositories.

I wish it clearly understood that I employ non-operative treatment only in cases with localizing abscess with diffuse peritonitis. To treat early intra-appendiceal appendicitis medically is a hazardous venture; as well might one tie a halter about the little patient's neck. It is like the game of heads I win, tails you lose. Medical treatment should have no more place in the treatment of these early cases than it has in hare-lip or cleft palate. Its mortality is twice that of the operative, and in cases of recovery it is difficult to convince the parents of the necessity of interval operation. Furthermore, when recurrence does occur, surgical help may not be at hand.

---

[17] Deaver, H. C.: Ann. Surg., 1909, xlix, 619.

Operation is even more suitable for children than for adults, since their kidneys and cardiovascular system have not suffered through alcohol or age, and hypostatic pneumonia seldom occurs. In suppurative cases the appendix may be removed when it lies free or presents conspicuously in the wall of the abscess. On the other hand, when the abscess is large and the appendix not directly visible, and when its removal necessitates extensive disseverance of adhesions, it should not be disturbed, because of the probably already weakened and exhausted condition of the child, and the chance of diffusing pus over the abdomen. Thus, in twenty-six of my cases, the appendix was not searched for, but was removed subsequently. When pus is already diffused throughout the abdominal cavity, flushing the peritoneum is decidedly contra-indicated. Accessible pus, however, may be mopped away and copious drainage provided through the original incision and through counter incisions. In "clean" cases, I employ a small gridiron incision, since it reduces the chances of a post-operative hernia to a minimum. The stump of the appendix must be carefully disposed of by tucking under, and cecoplication must be so performed that there will be no liability of the sutures yielding, thus permitting reinfection of the peritoneum by the stump. As a routine measure a glass tube should be passed into the pelvic basin to explore for fluid, lest a pelvic collection be overlooked, and this precaution may be rendered doubly effective by rectal examination previous to operation.

The post-operative treatment of appendicitis is highly important. This begins immediately on the patient's removal from the operating table. If drainage has been required, the patient should be propped upright in bed, in the Fowler position. I do not maintain this position for more than thirty-six hours, for fear the intestines, already crowded into the pelvis by gravity, adhere to each other and cause intestinal obstruction. Enteroclysis, I am sure, is most beneficial for pus cases.

Nausea, spitting up, and vomiting after operation, usually yield to the stomach-tube. If these are persistent, however, and if there is a sudden severe pain becoming paroxysmal, intestinal obstruction has developed, as these are the initial symptoms.

The classic symptoms of intestinal obstruction, projectile vomiting, great distention, and retention of feces and gas, must not be permitted to appear, since they bring forlorn hope to the operating-table. These are not the symptoms of intestinal obstruction, but are those of a toxic peritonitis, the result of intestinal obstruction. I found the temperature and pulse to be of but little significance in these cases. When operating, if no definite constricting band is found, and the adhesions are numerous, the best procedure is to establish lateral anastomosis to circumvent the obstructed area. Accordingly, I established ileocolostomy in one of my cases of intestinal obstruction. In two other cases the same procedure was indicated at the primary operation for prophylaxis of the partial obstruction, which was present, becoming complete. In the one, two knuckles of ileum had adhered so as to produce partial obstruction by agglutination, and ileocolostomy was necessary. In the other, enterorrhaphy to close a perforation of the ileum so narrowed the intestine that ileocolostomy was likewise performed. I have prepared a table showing sixteen cases of intestinal obstruction operated on with one death, that of a boy, admitted on the fourth day of his illness, who had developed a frightful peritonitis and, after a plucky fight of eighty-five days, in the course of which he developed bronchopneumonia and subphrenic abscess and endured three operations, finally succumbed to that octopus of surgery, universal abdominal adhesions.

Secondary abscess occurred in twelve of my cases, and was subphrenic in six. Cases showing diffuse peritonitis at operation must be watched carefully throughout the first month of the post-operative period for evidence of this complication. Protracted elevation of temperature, together with high leukocyte count and local signs, usually indicate secondary abscess. Subphrenic abscess fixes the diaphragm, produces rigidity of the overlying muscles, pushes the liver down, causes diaphragmatic pleurisy, and makes the patient profoundly septic. In the series of intestinal obstruction, two secondary abscesses were found, one beneath the diaphragm and the other at the duodeno-jejunal flexure.

The amount of urine must be watched daily after operation, and the stools examined for blood and intestinal parasites. The heart and lungs should be examined daily, and the skin closely watched for prompt diagnosis of the eruptive fevers and the throat for diphtheria. Six of my patients developed contagious diseases during their convalescence.

As regards drainage, I employ it only when the exudate is purulent or in large quantity. I use gauze, with or without a glass or rubber drainage-tube. The objection to drainage, especially with tubes, is that it may cause inflammatory exudate predisposing to intestinal obstruction. Glass tubes are more suitable for the pelvis, but their rigidity is a drawback. One of my patients broke a glass tube in his pelvis. In three others the tube was found, when dressing, to be blocked by a plug of omentum. The glass tube is usually removed within three days, when the exudate becomes clear and small in amount. It is replaced by a rubber tube, which is removed within a week. Rubber tubes are also useful in draining pockets of pus through counter-incisions, and, in conjunction with gauze, for large collections. Gauze drains well for a few hours, but, after that, it is only protective in function and hinders, rather than favors, drainage. Over the drainage I place gauze dressings, wrung out in sterile salt solution, since thus they absorb discharges more readily than a dry dressing.

CONCLUSIONS

1. Appendicitis in childhood occurs with increasing frequency from birth to puberty, and is more common in males.

2. It runs a rapid and severe course in children more often than in adults. There is less tendency to the formation of strictures, but fecal concretions are more often found.

3. Enteric fever, intestinal catarrh and influenza may predispose to appendicitis. Other infectious or contagious diseases and nasopharyngeal troubles are hardly to be considered as etiologic factors.

4. In infants the symptoms of acute appendicitis are often scanty, irregular and misleading. Infantile appendicitis is more frequent than is generally believed, or than statistics. In older children even more regularly than in adults, acute attacks occur suddenly and stormily. Chronic appendicitis represents a focus of chronic autotoxemia, with all its attending evils.

5. All cases of abdominal trouble in children should be regarded as appendicitis until proved otherwise. Differential diagnosis must be made between appendicitis and intestinal catarrh or worms, right-sided pneumonia or sacro-iliac disease, ovarian cyst twisted on its pedicle, mesenteric cysts, cystitis and rectal abscess.

6. The prognosis in acute appendicitis is favorable, if the case is received early and if the appendix is removed early. If the patient is operated on within the first twenty-four hours, the mortality is practically nil. After this time, the prognosis rapidly becomes worse. In chronic appendicitis an acute attack with perforative appendicitis is always to be feared.

7. The result of this ideal in treatment is to maintain the mortality at nil. Early operation is the normal course to pursue.

8. In intra-appendiceal appendicitis the appendix with the entire diseased tissue can be removed with nothing but benefit to the patient.

9. Non-operative treatment is indicated in cases of localizing abscess with diffuse peritonitis. Opium and purgatives are absolutely contra-indicated. Cathartics must never be given unless it is absolutely certain that appendicitis is absent.

10. Operation is even more suitable for children than for adults.

11. Post-operative treatment is highly important. The Fowler position must not be maintained for more than thirty-six hours in drainage cases, lest intestinal obstruction develop.

12. Intestinal obstruction is ushered in by sudden, severe pain, becoming paroxysmal, and by nausea, spitting up and vomiting. Later symptoms arise in consequence of toxic peritonitis, the result of intestinal obstruction. The temperature and pulse are of but little significance in these cases. In the presence of numerous adhesions ileocolostomy is the best procedure.

13. Secondary abscess must be carefully watched for. It is revealed by a rise and continued elevation of temperature, with high leukocyte count and local signs.

14. Contagious diseases must be recognized at once.

15. Drainage is to be employed only when the exudate is purulent or in large quantity. By its presence, it produces adhesions and predisposes to intestinal obstruction. Glass tubes may be broken or plugged by omentum. Rubber tubes are valuable for their pliability. Gauze drains well at first, but later retards drainage. A wet dressing is the best for absorption.

STATISTICS

Number of cases	500
Number of deaths	23
Mortality (per cent.)	4.6

ABSTRACT OF DISCUSSION

DR. L. S. MCMURTRY, Louisville, Ky.: The subject of appendicitis has received such frequent and elaborate consideration in this section from year to year that it is difficult to present any phase of the subject which has not hitherto been discussed. The paper just read, however, brings forward an important and common incidence of this disease which has not had adequate attention. This disease is often overlooked in children, or the diagnosis made too late to obtain the best results from treatment. There are two conditions which render diagnosis exceptionally difficult: First, those anatomic variations found in childhood relating to the position and relations of the caput coli and appendix, developmental in character, detract from the classic local symptoms and are in consequence misleading. Second, in early childhood the patient is unable to lend the coöperation as to subjective symptoms afforded by adults, which is so valuable as a diagnostic aid. And again, the diagnosis is more difficult because in young children palpation is impracticable, especially deep palpation. Gentle rectal examination is a valuable aid to diagnosis, and will often disclose the nature of the disease.

The essayist has properly emphasized the importance of quick work in the operative procedure. The dangers of prolonged anesthesia and extensive manipulation are increased in operations in children, and hence the greatest expedition should be observed. In a large proportion of suppurative cases the appendix should not be searched for, the surgeon contenting himself with evacuation and drainage for the immediate good result. In a word, Dr. Deaver has advocated the same principles in children that should be applied to adult life, after diagnosis has been established. In my experience intestinal obstruction is more common after operation in children than in adults, and the early recognition of this sequel will do much to prevent a fatal result. The rule in diagnosis set forth by Dr. Deaver is an admirable one, and should be generally adopted, viz., that diagnosis of appendicitis should be assumed in cases of severe abdominal pain accompanied by fever, and, unless proved otherwise, should be treated as appendicitis. And finally, in acute inflammatory disease of the abdomen in children opium should not be given in the early stage of the disease. The use of opium and drastic cathartics is harmful and should be withheld.

Dr. Edgar A. Vander Veer, Albany, N. Y.: In my experience, based on a study of the cases occurring in the practice of my father and myself, I find that the disease is most general between the ages of ten and twenty. Before the age of ten years the cases are comparatively infrequent and not so easily diagnosed by the attending physician, because of the inability of the child to make known the exact location of the pain. The approach to and the commencement of puberty also seems to have a bearing on the subject, and may to some extent account for the increased number of cases recognized after the age of ten years. Our youngest case occurred in a boy, three and one-half years old, who was ill only six hours, but from whom a gangrenous appendix was removed. He complained of pain in the stomach, but the diagnosis was made chiefly on the rigidity of the right rectus muscle.

As the author says, a child often comes to the surgeon with a history of having had bilious attacks, and when such a history is given it is wise to entertain the possibility that there have been attacks of appendicitis. In fact, I have operated in several cases in which the only symptom complained of was an indefinite pain in the abdomen, accompanied by a history of the patient having had several bilious attacks, and invariably have found a diseased appendix to be the cause of the trouble. Differential diagnosis between appendicitis and the other conditions mentioned is not very easy, though very important, and can only be determined by a careful weighing of the symptoms.

When we obtain a history of a child having suffered for years from bilious attacks, taken suddenly with vomiting and an acute pain in the abdomen, no matter whether in the right inguinal region or not, but gradually converging to that point, with an increased leukocytosis and with rigidity of the right rectus muscle, without excluding any of the other conditions, we are safe in making a diagnosis of appendicitis.

As to the laboratory as an aid in diagnosis and prognosis, I have not found it of very much value as the decision must be made by the surgeon on the symptoms presenting at the time he sees the case, not delaying for an elaborate report from the laboratory, which delay might prove fatal in many instances. Of course, the most favorable time for operation is *in the first twenty-four hours* when the prognosis is very good indeed, but it is seldom that we see a case under such favorable conditions, it usually runs along anywhere from three to four days to a week. In all these cases I believe in immediate operation no matter whether the appendix has not as yet ruptured, whether the abscess has formed, or whether there is diffuse peritonitis present. Often in cases in which the patients are in desperate condition I have seen them recover after operation and in my opinion the prognosis lies not so much in the operation as in the postoperative treatment.

The average practitioner within the past five years has come to recognize the symptoms of appendicitis much earlier than formerly, the result being that cases come to operation much sooner and the danger of resulting complications is greatly lessened, so that the abscess cases and cases of general peritonitis, with their consequent complications, are also greatly lessened in number.

Children, as a rule, react quickly after operation and seem to have more resisting power against infection, etc., than people of middle age.

When we come to look over the entire situation, appendicitis, barring the difficulty of making diagnosis, is no different in children from what it is in adults.

Dr. M. M. Lucid, Cortland, N. Y.: Why can we not treat appendicitis as we generally treat other things, strictly on a basis of facts? In other words, why not believe what we see, and strive to be prepared to read the handwriting on the wall—on the inside of the abdominal wall—from external manifestations, and not be misled by irrelevant symptoms? It has been my experience as well as that of several surgeons to operate on patients with acute, progressive appendicitis who were ill in bed with other unassociated ailments.

Much as we have learned about appendicitis, we have yet to learn that we ought to treat it *precisely* as we treat cancer, that is, as a local disease. To wait for the development of constitutional symptoms, such as elevation of temperature increased frequency of pulse, *with high tension*—the development of tympanites, etc., is to trifle with death in defiance of the plainest teaching of experienced surgeons. Our ablest surgeons, whose experience covers many thousand cases, tell us that the actual pathology of the appendix is not reflected by the symptoms of the patient. Why then should the general practitioner presume on a limited degree of good fortune often mistaken for skill, decide offhand what cases are operable and what inoperable without recourse to a surgical consultation? Meanwhile let it be admitted that good medical treatment is far preferable to poor surgical treatment.

Appendicitis may occur in any section of the country, at any time, and in any individual. There is but one treatment for a progressive case of appendicitis namely, *operation, not* when fulminating peritonitis has developed, but long before the deadly infection has passed beyond control.

Some laymen and many physicians "dread operations" having in mind operations performed too late and under conditions which they do their best to perpetuate. They *do not* recommend operation except as a last resort life or death—unfortunately, such patients usually have both operation and death. We are deeply indebted to Morris, Fowler, Ochsner, Murphy, the Mayos, and a score of others, for their thoroughgoing studies of the treatment of peritonitis. Surgical prophylaxis is the watchword for the early treatment of suppurative peritonitis—just as one fire-proof building is worth a dozen fire engines. It is fair to assume that within a few years, the man who trifles with a case of progressive appendicitis will be classed with the one who applies a greasy nostrum to a mammary cancer.

Dr. Maurice Rosenthal, Fort Wayne, Ind.: As has been brought out by the paper, as well as in the discussion, the lack of drainage and the formation of adhesions with consequent intestinal obstruction have contributed to the immediate mortality in these cases. I attribute nearly all my mortality in appendicitis to obstruction and lack of drainage. You can *prevent bowel adhesions*, at least for some time, by the liberal application of petrolatum. Like paraffin, petrolatum is absorbed very slowly, possibly not at all. By *applying it in the area to be drained*, I have found that drainage is more prolonged and more profuse, and that the dangers of adhesions and obstructions can be greatly reduced thereby. I have used petrolatum by manual application to a limited area, in a few cases—the last four cases, I think, in which I operated. I got better drainage, more efficient drainage, and more prolonged drainage, and probably averted some of the dangers of adhesions from obstruction.

Dr. Herman Tuholske, St. Louis: There are without question certain principles thoroughly understood and known which govern the management of appendicitis in children. No one has done so much in this direction as Dr. Ochsner. We have learned considerable about the proper treatment of appendicitis *from him*. There are some things that are very clear today. Some twenty-odd years ago, when I had a very limited experience in operating for appendicitis, I said: "Make the diagnosis and then operate." I have several times since then changed my opinion, but have always *come back to the orig-*

inal idea. The point of greatest importance is that a diagnosis of appendicitis should not be based on any one symptom. There is no such thing as a pathognomonic symptom of appendicitis. Pain in the region of the appendix may mean something else. Not long ago a physician made a diagnosis of appendicitis for a man who was traveling in the East and urged immediate operation. The patient returned to St. Louis at once, suffering great pain at the classical point. He asked me to operate for appendicitis. I had him go to bed in the hospital. When I saw him in the morning, there was as beautiful a streak of herpes zoster as I have ever seen, occupying the line of pain. Recovery was prompt.

As to treatment, I believe in operation as soon as the diagnosis is made, unless there is a positive contraindication. In making a diagnosis we must be on our guard, because in the early hours in young children there may be something else brewing. I have seen three cases recently, in which I was called by competent internists to operate, and which occurred in children of five and six years, who within a day developed pneumonia. One of them was rolling around in bed moving his limbs freely. I examined the child and elicited no pain in the abdomen. I asked for ten hour's delay, and at the end of that time the doctor told me the child had an unmistakable attack of pneumonia. First, make a careful diagnosis and then act, but never harbor the idea that appendicitis patients do not die; nor should you operate on the strength of one symptom or a combination of indistinct symptoms.

When you are sure of your diagnosis and the patient is still in fair condition, operate at once. If you wait until pus is forming, then you must follow some other plan of treatment and use your best judgment in selecting the proper time for operation later in the interval. An appendix which has been inflamed must be removed some time.

Dr. John B. Deaver, Philadelphia: We have heard a great deal about race suicide within the last few years from one of our most distinguished citizens, but there is no one thing that contributes so largely to a decreasing population as does sterility, the result of pelvic appendicular peritonitis in young girls and young women.

PERSISTENT PATENCY OF THE DUCTUS ARTERIOSUS

DEGENERATION OF THE CARDIAC MUSCLE AND CORONARY ARTERIES, AND OF THE SINO-AURICULAR BUNDLE, FOLLOWED BY RUPTURE OF THE RIGHT VENTRICLE*

KATE CAMPBELL MEAD, M.D.
MIDDLETOWN, CONN.

One of the most interesting problems of physiologists to-day is concerned with the structure and action of the heart. So much experimental work has been done during the past few years on the cardiac muscle, nerves, valves, and blood supply, as well as on the arterial system, by means of measuring apparatus and surgical operations, that any extraordinary case of heart failure which can be studied during life and post-mortem should be made available for future reference, as an addition to our sum-total of knowledge of congenital anomalies, as well as of inflammatory disease.

It is for this reason that I have ventured to make a slight contribution to the literature on congenital cardiac malformation, which in this case was associated with a sequence of disorders of the heart and its valves, resulting in a rare condition of rupture of the right ventricle, and in the patient's death at the age of 26.

In presenting this report I must express my regret that no sphygmographic tracings or electrocardiograms were made from the heart, the arteries, or the veins; but a brief study of the conditions as a whole may not be unprofitable, although a full discussion of such a case would far exceed the limits of this paper.

REPORT OF CASE

History—The patient was a married woman. Of her early history there is little known; she told me she had always had rheumatism and backache, had suffered frequently from grip, and that her physicians in Berlin, Germany, said she had heart trouble since she was a little girl. Her parents and grandparents were healthy. I first saw her April 3, 1905, and her condition was as follows: Height, about 5 feet, 4 inches; weight, 120 pounds; body, plump; color, good; some acne on face; catarrh of throat and nose; lateral and anterio-posterior curvatures of the spine due to muscular weakness, simulating both scoliosis and kyphosis; aortic pulsation in the abdomen noticeable; heart enlarged 1 cm. to right and left, with a murmuring, noisy systolic murmur heard both at base and apex, extending to right of the sternum and almost to the axilla; lungs normal; bowels distended with gas; diarrheal movements; stomach larger than normal; liver normal; left kidney in left groin; pelvic organs normal; urine normal.

After a summer of rest and hygienic life the cardiac murmurs nearly disappeared, but the patient continued to suffer from backache, diarrhea, and catarrh of the throat. The following year she went through a successful pregnancy in better health than usual, even omitting colds and grip. During the summer of 1907 she had a nervous strain which was followed in the early autumn by a condition of flabby muscles and flabby heart, with loud systolic murmur over the pulmonary artery in the third space, and a strong thrill felt over the third and fourth interspaces at the right of the sternum, and frequent palpitations. Her intestinal indigestion was very troublesome, and the facial acne most annoying. Hygienic treatment, baths, massage, careful diet, and occasional doses of codein gave considerable relief, while digitalis, even in minute doses, caused most uncomfortable bounding and beating of the arteries all over the body.

At the end of December, 1907, I referred the patient to Dr. Thayer of Baltimore, who sent me the following diagnosis:

"There is evidently a congenital malformation, but one which from her history and condition, may well be compatible with a long life. The long machinery murmur over the right ventricle with systolic accentuation, together with the accentuation of the second pulmonic sound, and the rather large right side suggest a septum defect (ventricular). This lesion is also more compatible with long life than most other cardiac defects. A striking feature of this case is the fact that the murmur is so loud at the base and in the first left interspace, and that the accentuation high up is late, a late systolic, almost a diastolic accentuation, but the murmur still continues throughout both cycles of the heart with the heart sounds heard, as it were, superimposed. The loudness of the murmur high up and the change in its accentuation would suggest to me an open ductus arteriosus."[1]

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

[1] *I have taken the following notes from Dr. Thayer's memoranda:* "Weight, 121½. Color is good. General nourishment good. Pulse, 21 to the quarter at the beginning of examination, regular. Radial, not palpable. Pressure, by estimate, 120-25; measurement, maximum, about 115; minimum not easy to estimate. Thorax, symmetrical. Costal angle about 90. Movements, equal. Resonance and respiration clear in front. Back perfectly clear. Heart, P. M. I. in the fifth space, approximately normal position, 8.6 cm. from the median line, begins above in the second space and extends about 5.5 cm. to the right of the median line in the fourth space. No thrill in the precordial region, although the impulse is rather well felt in the second and third left spaces. Sounds, at the apex, first clear excepting for a soft systolic gradually fading away. Second, clear, followed by a very soft diastolic. As one reaches the fourth space a characteristic long machinery sound with systolic accentuation lasting through the whole cycle is audible. This is loudest in the third space, well heard in the second, also over the right side and out over the left chest. In the first left space under the clavicle the murmur was also very long and well heard with late systolic or, perhaps, even diastolic accentuation. The second pulmonic is loud and sharp. The second aortic is also of fairly good intensity. Right kidney descends below the costal margin. Liver is just felt descending below the costal margin on deep inspiration; no enlargement. From the character and position of the murmur one is justified in assuming a septum defect, and from the murmur which is heard up under the clavicle in so high a position, an open ductus Botalli."

During 1908 the patient was fairly well so long as she lived a quiet life and refrained from lifting heavy objects, which gave her pain in the abdomen and slight palpitation of the heart. In November she suffered from another attack of influenza, with tonsillitis, slight bronchitis, and a little pleurisy at the base of the left lung. The mild fever left her very much exhausted, with a hoarse voice and irritating cough, due apparently to a large lingual tonsil and relaxed uvula, but with no new cardiac symptoms, either objective or subjective She continued hoarse, and although the cough was gone by the end of February, 1909, her heart began to be more dilated and to have the murmurs and irregularity first heard in 1906. After a visit to Lakewood, in April, however, she gained several pounds in weight and felt better, although there was now in addition to the hoarseness a peculiar thin voice.

On April 22, 1909, I referred the patient to Dr. E Terry Smith of Hartford, who reported a paralysis of the left vocal cord, caused probably by pressure from the heart on the abductor fibers of the left recurrent laryngeal nerve

A report by Dr. Goodale of Boston, a week later, confirming Dr Smith's diagnosis, was as follows:

"April 30, 1909 Left vocal cord fixed in median line, immovable on phonation and respiration. Left arytenoid moves inward slightly on phonation. There is no evidence of thickening or irregularity in or about the arytenoids.

'The preservation of motion in the left arytenoid on phonation is due to the contraction of the interarytenoid muscle, indicating preservation of function in the superior laryngeal nerve This movement, together with the absence of irregularity or thickening in the left arytenoid joint, renders it probable that there is no ankylosis in the joint itself. It is, of course, possible that Mrs X.'s abductor paralysis arises from grip or laryngitis, but this is, to my mind, less probable than that it arises from pressure along the course of the nerve, for the reason that general infections do not, as a rule, affect the abductor fibers alone of one cord."

The patient was then sent to Dr Percy Brown of Boston, who made a Roentgen diagnosis of her heart as follows:

"The base of the heart, examined from both behind and in front, presents an undue and abnormal bulging on its left side, which markedly changes the shadow usually recognized as the normal in form and size This appearance is in close juxtaposition with the descending arch of the aorta, and may to a certain extent involve that structure The dilatation is general, however, rather than a sharply localized expansion, which would tend to rule out the likelihood of aneurism as being the etiologic factor I am rather of the opinion that it is due to a hypertrophied and dilated left auricle, secondary to an insufficient mitral valve This dilatation is the only apparent cause of the mechanical inference with the function of the recurrent laryngeal branch"

For one month, while the patient was living quietly and taking simple vocal lessons, the heart symptoms again improved and the voice became nearly normal, but on June 1 she complained, when walking, of severe paroxysmal pains in the abdomen and legs, especially in climbing stairs or going up hill. The heart was not then larger than usual and the murmurs were faint, pulse 80, systolic blood-pressure was 118, and hemoglobin normal urine normal On June 5 the apical mitral murmur of 1906 returned, and the left area of dulness extended 3 cm to the left of the nipple; pulse 100 On June 11 the pulse was 70 and regular, but a hard, suffocating pain was centered in the stomach and abdomen, at times accompanied, when walking was attempted, by severe pressure below the diaphragm This persisted for one week, when some edema was noticed in the face and abdomen; the patient passed 500 c c. of urine in eighteen hours full of urates, but containing no albumin, the specific gravity being 1040; her radial blood-pressure was 140 Digitalis being contraindicated, warm Nauheim baths were given, plus strophanthus and diuretin: the urine increased to 900 c.c. for a few days and the abdominal girth was reduced 6 cm.; at the same time the heart sounded stronger, and the edema left the face. Then, however, the stomach became irritable, the heart began to be very irregular with loud aortic murmur, and all baths and heart tonics were replaced by calomel, Epsom salt, and codein. On July 5, the voice again showed signs of the former paralysis, and a laryngeal cough was almost constant; the pulse was 105, pressure 130; the legs were very much swollen; the stomach and bowels were full of gas and the urine scanty. On July 9 she could not rest for a moment, owing to the laryngeal cough and cardiac discomfort; at 5 a. m of the 10th she broke into a profuse cold perspiration; at 7 a. m. she seemed faint and lapsed into a short stupor, after which until death no pulse could be detected at the wrist, even though hypodermic stimulants were freely injected, the carotid pulse was 104, very irregular, and the patient had difficulty in breathing, was restless and thirsty all day, dozing at brief intervals; she took a little nourishment and passed about 7 ounces of thick urine. At 10 p. m. she had another period of fainting with profuse perspiration and gasping, after which she could with difficulty be aroused, her speech was somewhat incoherent and thick, and she was still very restless. At 12.55 a. m., after swallowing a few drops of liquid, she suddenly threw up her arms, opened her eyes widely, gasped once or twice, and died.

So much for the patient's symptoms while under my care. Her earlier medical history is very meager. She was born in Berlin, Germany, a perfectly normal birth and a typically healthy baby, it was thought, but the physicians of her childhood are dead. A letter from Dr. Max Ph. Meyer, Geh.-Sanitatsrath, gave the following information: There was a systolic murmur over the mitral valve, which was louder during the fever of measles in 1895. In 1899, after a period of fatigue, the aortic valves were not found to be free from chronic inflammation, the tones not being quite clear. A note from Dr. Geheimrath Wolf says "After two examinations, I found a good compensation in the heart (*ein gut compensierter Herzfehler*)."

Owing to the peculiarity of the symptoms in this case and the lack of early history, together with her early death, it seemed wise to seek for a postmortem diagnosis in order to make it possible to use for future cases whatever could be learned of the exact causes for the cardiac weakness in this patient Dr. Jessie W. Fisher, pathologist to the State Asylum for the Insane at Middletown, Conn., performed an autopsy with the following result:

"*Necropsy*—Some twelve hours post-mortem. Rigor mortis moderate The patient was a well-developed, well-nourished, but undersized woman, 26 years of age, with distended abdomen, edematous feet and legs, and cyanosed face and neck. Panniculus adiposus was 3 cm. in thickness. The stomach was much distended with gas, and the abdominal cavity contained at least 2,000 c c. of straw-colored fluid.

"Thorax: Both parietal and visceral layers of the left pleura were adherent laterally, posteriorly, and to the diaphragm. The right pleura was free

"Left Lung: Weight was not taken. The lower lobe showed hypostatic congestion, the remainder of the lung being crepitant, presenting no abnormalities. Bronchi free and unobstructed.

"Right Lung: Lower lobe showed a slight amount of hypostatic congestion. Otherwise the tissue was normal.

"Heart: The pericardium was smooth and glistening and covered by a very thin layer of fat. The pericardial sac contained about two ounces of fluid blood. When the sac was opened, three ruptures on the right ventricle appeared. parallel to the descending branch of the anterior coronary artery, and 3 cm. to 4 cm. to the right of it. The first was 2.5 cm. from the pulmonary valve, and was 9 mm. in length, slit-like in appearance, involving only the superficial fibers. The second was near the apex of the heart and measured 15 mm. in length externally and penetrated the ventricle by a minute aperture. The third, immediately below and on the apex of the right ventricle, was 15 mm. in length externally, but presented only a pin-point opening internally.

"At autopsy the ruptures seemed to be in the left coronary artery, but on later dissection of epicardial fat the first rupture lay 3 cm. to the right, and the second and third ruptures 4 cm. to the right of the left coronary.

"The ruptures lay in almost a straight line with each other, and the blood had separated the epicardium above and below them, giving the appearance of a thrombosed vessel.

"The ductus arteriosus was patent and had developed into a good-sized vessel, with walls 1.5 mm. in thickness. The diameter of the opening into the aorta was 1 cm., and into the pulmonary artery was 4 mm., where it was surrounded by a thickened ring, and slight fold of membrane. It was funnel-shaped with large end in aorta and 1 cm. in length. The aortic opening of the duct was located opposite the left subclavian artery.

"Heart weighed 395 gm. (Osler gives the weight of a normal female heart as 250 gm.)

"The heart was in systole. The right side was dilated and hypertrophied, containing fluid blood. The right auricle and ventricle were nearly twice as large as normal, and the right ventricular wall was almost as thick as the left, which was also hypertrophied. The foramen ovale was closed, but the fossa was 2.5 by 1.5 cm. At its base the Eustachian valve formed a membranous valve 1.5 cm. in width and 4.5 cm. long, containing muscle fibers.

"Beneath the epicardium of right ventricle there was a marked accumulation of fat, which covered the myocardium and coronary arteries completely.

"The myocardium was thickened, pale in color, and flabby, especially in the right ventricle.

"The auriculoventricular node was well marked, lying between the fossa ovalis and enlarged Eustachian valve. The fibers seemed to pass to the left, where they were lost.

"The ventricular septum was thickened without any indications of defect.[2]

"The pulmonary artery was almost twice the size of the aorta; it was soft, and the aorta slightly thickened around the duct and valve. Insertion of the duct into the aorta was almost at a right angle.

"The cusps of the pulmonary valve were smooth, thin, transparent and competent. The cusps of the tricuspid valve were smooth, glistening and competent. The aortic cusps were slightly thickened throughout and the aortic opening stenosed. The aorta showed plaques of sclerosis around the valve. The cusps of the mitral valve showed slight thickening along the free borders. This opening was small and stenosed. The descending branch of the left coronary was small and walls thickened, but not calcareous. The right coronary was larger than the left, and like it thickened throughout its course.

"Measurements: Tricuspid, 11.5 cm.; mitral, 8.5 cm.; pulmonary, 7.0 cm.; aortic, 5.0 cm.; left ventricle, 1.3 cm.; right ventricle, 1.1 cm.

"Larynx and Trachea: The recurrent laryngeal nerve was normal in appearance, as was the vagus. The larynx, vocal cords and trachea presented no evidence of pathologic change, except for a small tracheocele situated just above the bifurcation of the trachea. Microscopically, the recurrent laryngeal nerve showed no degeneration with Marchi's stain.

"Microscopic examination of muscle near site of rupture: eosin and methylene blue sections stained poorly, nuclear outline faint or nuclei entirely absent. Muscle fibers separated from each other, and intervals filled with red blood cells. Cross striations very distinct. Some fragmentation. Soudan III sections showed muscle cells loaded with fine granules of fat. Hematoxylin and eosin same as methylene blue and eosin.

"Kidneys: The kidneys were pale in color. The capsule peeled easily, leaving a smooth surface. On section the tissue was pale; the cortex was a trifle narrower than usual, but the markings were distinct. On microscopic examination of the kidneys, capsule of Bowman showed considerable thickening and swelling of the cells lining the capsule, and the epithelial cells lining the tubules were swollen and granular. All of the vessel walls showed extreme thickening.

"Liver: The liver was slightly enlarged, but was not removed for examination.

Anatomic Diagnosis.—"Rupture of the heart and sclerosis of coronaries, patent ductus arteriosus, aortic and mitral stenosis and chronic endocarditis of aortic and mitral valves, atheroma of aorta, hypertrophy and dilatation of right heart, tracheocele, slight chronic nephritis, fatty degeneration of myocardium."

Having the autopsy report, it was not difficult to explain the symptoms during the life of the patient, for, doubtless, the primary cause of all the pathologic findings in this heart was the persistent patency of the ductus arteriosus. Dr. H. Gideon Wells[3] has found in all literature only forty-one cases of uncomplicated ductus arteriosus reported with corroboration of the diagnosis at autopsy, and in only twenty of these cases did the subject reach maturity.

In Maude E. Abbott's[4] tabulated series of 19 cases of patent ductus arteriosus, the oldest patient was 53, the youngest 6 years old; nine were males, ten females. Out of 106 cases of patent ductus arteriosus, there were eighty-seven cases complicating the defects, leaving the above-mentioned nineteen cases which were proved at autopsy to have the simple defect of patent ductus arteriosus. She gives as causes for this defect the loose musculature of the artery, the sudden change in cardiac blood-pressure at birth, and the alterations in relative position of the ductus and great vessels due to stretching, etc. The usual funnel shape of the ductus is caused by the back pressure of blood from the aorta into the pulmonary vein, but where there is congenital aortic stenosis the current should be reversed. The pulmonary artery and the right ventricle must naturally dilate, and arteriosclerotic patches are not uncommon in the neighborhood of the patent duct and aorta. As for symptoms of a patent ductus arteriosus there may or may not be a systolic thrill, but the "long machinery murmur" is nearly always produced, and the accentuated second pulmonary sound distinguishes this anomaly from pulmonary stenosis. Several other writers have also mentioned the paralysis of the left recurrent laryngeal nerve, due to pressure on that nerve by the patent duct or enlarged auricle, which causes a laryngeal spasm prolonged for hours at a time, giving the right ventricle no time to recover from the added resistance to its contraction, and therefore aiding permanent dilatation of the right side of the heart with all its attendant evils.

My case differed in many points as to symptoms from that reported by Dr. H. Gideon Wells. His patient was 42 years old, suffered from symptoms of gall-duct disease or of acute yellow atrophy of the liver, and died from a hemorrhage of the bowels with a temperature of 106, after a few days in the hospital. The previous history of his case was negative, and the examination of the heart when the patient entered the hospital showed systolic murmurs from the second to the sixth right interspace, so that a tentative diagnosis was made of aortic dilatation with enlarged heart. In the case of my patient, there was no other disease of the body and no symptoms not explained by the condition of the heart, which, however, was well hypertrophied and did not appear by percussion, palpation or auscultation to be unequal to its task. This patient was very susceptible to influenza, having one or two attacks every year. These attacks always increased temporarily the cardiac irritation, and the murmur was at such times much more noticeable than at other times.[5] In 1906, when the patient went through a successful pregnancy, the mur-

---

[2] The thickness of right ventricle wall is normally 4-7 mm.; left ventricle, 20-25 mm.; left auricle, 3 mm.; right auricle, 2 mm.

[4] Abbott, Maude E.: Statistics of Congenital Cardiac Disease (400 cases analyzed), Osler's Modern Medicine, iv, 396.

[5] Schlagenhaufer's case of acute aortic endocarditis from the influenza bacillus in a case of patent ductus arteriosus suggests, along with my case, the possibility of the infection from influenza being more virulent than in ordinary cases.

murs were very slight, not recurring until after a nervous strain six months later.[6]

It is probable that our patient might have had no symptoms from the large patent ductus arteriosus if she had had no influenza and no other subsequent cardiac complications. Death from a patent duct is usually thought to occur in infancy, although the condition is one which might be overlooked in autopsy, and 9 out of 41 patients whose cases are reported by Wells lived more than forty years.

The characteristic signs of patent ductus arteriosus are in the main those indicated by Dr. Thayer after examining our patient. Osler's[7] terse symptomatology of a persistent ductus Botalli is as follows: "Loud, especially vibratory, systolic murmurs, with the point of maximum intensity over the upper third of the sternum, associated with a lack of marked symptoms of hypertrophy of the left ventricle." Thayer suspected also a septum defect on account of the character of the murmur over the third and fourth space, but this defect was not found on autopsy. Communication between the aorta and pulmonary artery might cause much the same symptoms as from the communication between the auricles. Their etiology is different, but the physical signs of hypertrophy with systolic murmurs at apex, and generally a diastolic murmur, or continuous murmurs[8] are common to both conditions. A septum defect is, however, frequently found in hearts in which there is also patent ductus arteriosus. W. Langdon Brown[9] says: "The deficiency in the exit of blood from the right ventricle will be made good to some extent by the ductus arteriosus remaining open."

Let us now look at the patient's subjective symptoms, as explained by the condition of the heart at the autopsy, and then at the objective symptoms which called forth various hypotheses.

For the last five years of her life the patient complained frequently of palpitations of the heart, sometimes at night, sometimes on exertion. It is possible to explain these symptoms by the mitral stenosis, since out of seventy-three cases of irregularity of the heart, Lewis found that 52 per cent. were instances of mitral stenosis. In many of these patients symptoms of valvular lesion were absent, the patient complaining of short-windedness, fluttering in the chest or neck, and gastric discomfort, the palpitations sometimes occurring in the middle of the night. Such was the case in my patient, the mitral lesions at times being impossible to define, but owing to the slight sclerosis of the mitral valves, there was at times some stenosis of that orifice, which would cause an increase of the interauricular pressure and eventually a condition of fibrosis of the auricles as well as in the ventricles. Lewis[11] says that it is possible that fibrosis by interfering with the circulation in restricted areas of the musculature sets up a state of irritability. Anemia of the muscle does the same thing, and may also result in extra systoles, and more or less permanent irregular tachycardia. "Unexpected death in patients with fibrotic hearts is a well-recognized fact." The aortic murmur, not always present, was caused by an incompetent thickened edge of one cusp of its double valve. Osler[12] thinks that this condition is generally well compensated, and may not shorten life. Broadbent, on the contrary, finds that 40 years is about the limit of life in this condition. Where there is any sclerosis of the aorta, however, there is apt to be a narrowing of the orifice of the coronary arteries. Sudden death may be caused by the blocking of one of these coronary arteries, or there may be a more deliberate sclerosis or a narrowing of the coronaries, which leads to fibroid degeneration of the cardiac muscle and eventually to fatty infiltration or fragmentation of the muscle fibers.

In regard to the degeneration of the coronary arteries, Abbott says:

> I believe that the commonest site for rupture of the cardiac muscle is on the anterior wall of the *left* ventricle [in our case it was the *right*] near the interventricular septum, about the junction of the lower and middle thirds, and the reason that this is the "seat of election" is because this area is supplied by the descending branch of the anterior coronary artery (the artery of the septum), which is a very common branch to undergo thrombosis, or embolism, thus leading to infarction of the supplied area of heart muscle. This vessel has been called the artery of sudden death, because disease of it is so frequently followed by serious results.[13]

In this connection an interesting question arises: Was the intense pain in the legs and abdomen of this patient due to sclerosis of the coronaries and referred to the abdomen instead of being felt in the heart? Or may there have been a sclerosis of the femorals with intermittent claudication, as well as sclerosis of the aorta and coronaries? The victims of angina may be due to a chronic arteritis in the gastric and mesenteric vessels, as well as to the heart. The radial blood-pressure in my patient never exceeded 140, but it is said that even low blood-pressures may co-exist with early arteriosclerosis. Certainly the intense throbbing in the abdominal aorta ought to have shown a higher pressure there than that in the radials.[15] Osler[16] says that spasm or narrowing of a coronary artery, or even of one branch, may so modify the action of a section of the heart that it works with disturbed tension, and there may be stretching and strain sufficient to arouse painful sensations, like the intermittent claudication of the arteries of the legs in a case of cramp.

At the autopsy there was thought to be a condition of thrombus of the anterior coronary artery with rupture in three places, but on careful dissection and microscopic examination the arteries were found to be unruptured, and it was the muscle of the right ventricle at a distance of 3 or 4 cm. from the artery, parallel with it, which ruptured, close to the interventricular septum where its circulation was probably the poorest. Abbott writes that this is a rare condition. She says:

> "We have four cases of rupture of the heart in this museum, in three of which the seat of rupture is in the situation above described, i. e., the left ventricle wall. Another possible explanation may be that the auriculoventricular bundle of His is distributed so extensively in the septum that disease of the artery supplying the septum may be productive of more serious disturbance than that of the artery in another part of the heart."

There was no sudden pain in my patient's case to note the formation of a thrombus, only restlessness and anxiety, followed by collapse, when the heart ruptured, not only once but three distinct times. The patient's father died probably from thrombosis of the coronaries several days after an operation for appendicitis, and as Blumer[18] suggests, there may be an inherited tendency to the production of thrombogen or thrombokinase. The effect of ligation of the coronary artery must be similar to thrombosis. Lewis says:[19]

---

[6] One such case is reported in which the diagnosis of patent ductus arteriosus was made in infancy, and again ten years later, and also at the age of twenty years, when Balfour confirmed the diagnosis, after which time the condition began to disappear until, at the age of thirty-five the lesion seemed to have healed entirely.

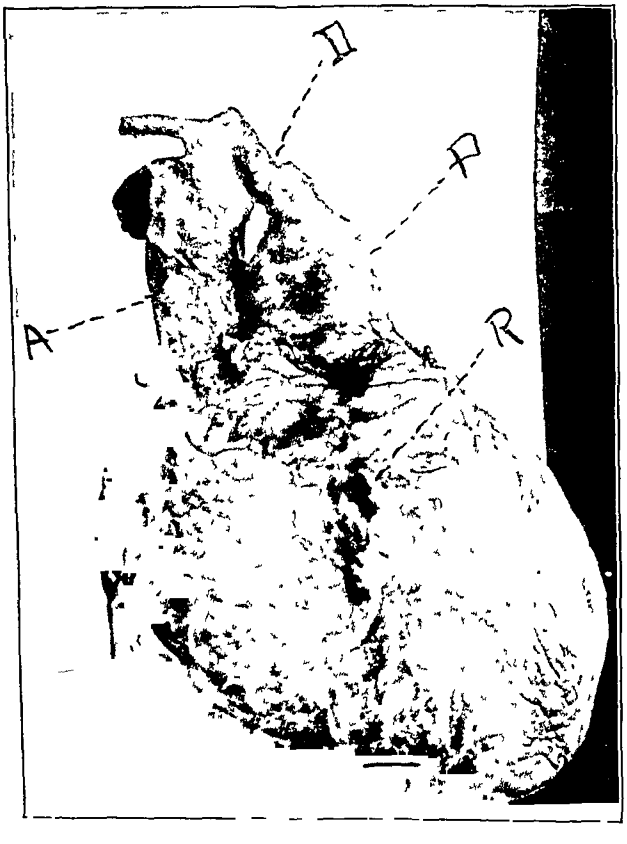

Fig 1.—Heart from subject with persistent patent ductus arteriosus; A, aorta; D, ductus arteriosus; P, pulmonary artery; R, ruptured right ventricle

> In the case of the right coronary, the area devascularized includes the right auricle and the greater part of the right ventricle. The muscle involved blanches and then becomes livid. The right auricle continues to beat less and less strongly, while the ventricle follows even less strongly to final fibrillation. Tachycardia was obtained in nine out of the twelve cases of right coronary artery ligated, cardiac irregularities most often following obstruction of this artery, and paroxysms occurring in from fifteen to sixty minutes after interference with the vascular supply, the paroxysms varying from a few seconds to thirty-five minutes in duration But if tachycardia is caused by a lesion in the cardiac muscle of the right ventricle itself, independently of nervous control, heart-block and a stop of the auricular beat can be also caused by irritation of the vagus

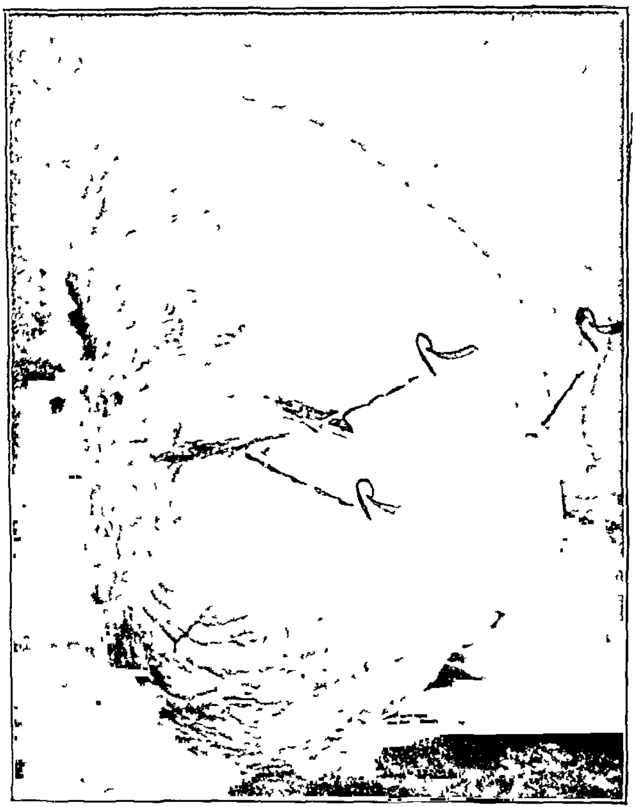

Fig 2.—Rupture seen from apex of heart.

Therefore, in this case, the anemic condition of the cardiac muscle, or of the bundle of His, caused by a lack of blood-supply from the sclerosed right coronary artery, may have been the cause of the palpitations and discomfort, while the dilatation of the stomach and intestines may have produced pneumogastric irritation which further increased the cardiac irritability, resulting in fibrillation of the ventricle and sudden death from ventricular exhaustion. The rate of rhythm of the ventricular contraction varies from 140 to 420. In my patient the pulsation in the left carotid was from about 160 to a beat too rapid to count, followed by sudden stillness. At the autopsy the blood found in the pericardial sac amounted to only 60 c.c., too little of itself either to stop the heart by pressure or anemia, many a stab wound of the heart being larger than all of the ruptures in the right ventricle. Therefore, it seems to me that we may be justified in attributing death ultimately in this case, to the trouble in the sinoventricular conducting system[20] rather than to the rupture, and that neither the patent ductus arteriosus nor the aortic stenosis would have been incompatible with long life. In all the cases of heart-block or extrasystole which have come to autopsy, there have been shown either gummata, anemic necrosis on account of thrombosis of the nutrient arteries, fibrosis, new growth, atheroma, or fatty infiltration.[21] The common cause is the same, i. e., interference with the conducting bundle (the auriculo-ventricular bundle), or its node.[22] This is probably one of the reasons why digitalis failed to be of service in the case in question, and explains the murs were very slight, not recurring until after a nervous strain six months later.[6]

[20] Retzer has renamed the bundle of His the sinoventricular conducting system This he considers a neuromuscular apparatus possibly connected with the sympathetic ganglia, the end organs of the conducting system being surrounded by a plexus of non medullated nerves Retzer Anat Rec, ii, 149, Johns Hopkins Hosp Bull, 1908, p 208

[21] Thomas Lewis in a recent article on auricular fibrillation has formulated the following data as to the action of digitalis "Digitalis retards the ventricular rate in clinical auricular fibrillation by enhancing a previously existing auriculoventricular heart-block. The rapid and irregular impulses showered on the ventricle from the fibrillating auricle are hindered in their passage from one chamber to the other by the action of drugs of this class The influence of digitalis is exerted, directly or through the vagus, on the junctional tissues between auricle and ventricle"

[22] Brown, W. L. Physiological Principles in Treatment, p. 231.

It is probable that our patient might have had no symptoms from the large patent ductus arteriosus if she had had no influenza and no other subsequent cardiac complications. Death from a patent duct is usually thought to occur in infancy, although the condition is one which might be overlooked in autopsy, and 9 out of 41 patients whose cases are reported by Wells lived more than forty years.

The characteristic signs of patent ductus arteriosus are in the main those indicated by Dr. Thayer after examining our patient. Osler's[7] terse symptomatology of a persistent ductus Botalli is as follows: "Loud, especially vibratory, systolic murmurs, with the point of maximum intensity over the upper third of the sternum, associated with a lack of marked symptoms of hypertrophy of the left ventricle." Thayer suspected also a septum defect on account of the character of the murmur over the third and fourth space, but this defect was not found on autopsy. Communication between the aorta and pulmonary artery might cause much the same symptoms as from the communication between the auricles. Their etiology is different, but the physical signs of hypertrophy with systolic murmurs at apex, and generally a diastolic murmur, or continuous murmurs[8] are common to both conditions. A septum defect is, however, frequently found in hearts in which there is also patent ductus arteriosus. W. Langdon Brown[9] says: "The deficiency in the exit of blood from the right ventricle will be made good to some extent by the ductus arteriosus remaining open."

Let us now look at the patient's subjective symptoms, as explained by the condition of the heart at the autopsy, and then at the objective symptoms which called forth various hypotheses.

For the last five years of her life the patient complained frequently of palpitations of the heart, sometimes at night, sometimes on exertion. It is possible to explain these symptoms by the mitral stenosis, since out of seventy-three cases of irregularity of the heart, Lewis found that 52 per cent. were instances of mitral stenosis. In many of these patients symptoms of valvular lesion were absent, the patient complaining of short-windedness, fluttering in the chest or neck, and gastric discomfort, the palpitations sometimes occurring in the middle of the night. Such was the case in my patient, the mitral lesions at times being impossible to define, but owing to the slight sclerosis of the mitral valves, there was at times some stenosis of that orifice, which would cause an increase of the interauricular pressure and eventually a condition of fibrosis of the auricles as well as in the ventricles. Lewis[11] says that it is possible that fibrosis by interfering with the circulation in restricted areas of the musculature sets up a state of irritability. Anemia of the muscle does the same thing, and may also result in extra systoles, and more or less permanent irregular tachycardia. "Unexpected death in patients with fibrotic hearts is a well-recognized fact." The aortic murmur, not always present, was caused by an incompetent thickened edge of one cusp of its double valve. Osler[12] thinks that this condition is generally well compensated, and may not shorten life. Broadbent, on the contrary, finds that 40 years is about the limit of life in this condition. Where there is any sclerosis of the aorta, however, there is apt to be a narrowing of the orifice of the coronary arteries. Sudden death may be caused by the blocking of one of these coronary arteries, or there may be a more deliberate sclerosis or a narrowing of the coronaries, which leads to fibroid degeneration of the cardiac muscle and eventually to fatty infiltration or fragmentation of the muscle fibers.

In regard to the degeneration of the coronary arteries, Abbott says:

> I believe that the commonest site for rupture of the cardiac muscle is on the anterior wall of the *left* ventricle [in our case it was the *right*] near the interventricular septum, about the junction of the lower and middle thirds, and the reason that this is the "seat of election" is because this area is supplied by the descending branch of the anterior coronary artery (the artery of the septum), which is a very common branch to undergo thrombosis, or embolism, thus leading to infarction of the supplied area of heart muscle. This vessel has been called the artery of sudden death, because disease of it is so frequently followed by serious results.[13]

In this connection an interesting question arises: Was the intense pain in the legs and abdomen of this patient due to sclerosis of the coronaries and referred to the abdomen instead of being felt in the heart? Or may there have been a sclerosis of the femorals with intermittent claudication, as well as sclerosis of the aorta and coronaries? The victims of angina may be due to a chronic arteritis in the gastric and mesenteric vessels, as well as to the heart. The radial blood-pressure in my patient never exceeded 140, but it is said that even low blood-pressures may co-exist with early arteriosclerosis. Certainly the intense throbbing in the abdominal aorta ought to have shown a higher pressure there than that in the radials.[15] Osler[16] says that spasm or narrowing of a coronary artery, or even of one branch, may so modify the action of a section of the heart that it works with disturbed tension, and there may be stretching and strain sufficient to arouse painful sensations, like the intermittent claudication of the arteries of the legs in a case of cramp.

At the autopsy there was thought to be a condition of thrombus of the anterior coronary artery with rupture in three places, but on careful dissection and microscopic examination the arteries were found to be unruptured, and it was the muscle of the right ventricle at a distance of 3 or 4 cm. from the artery, parallel with it, which ruptured, close to the interventricular septum where its circulation was probably the poorest. Abbott writes that this is a rare condition. She says:

> "We have four cases of rupture of the heart in this museum, in three of which the seat of rupture is in the situation above described, i. e., the left ventricle wall. In a recent case of rheumatic endocarditis, Mackenzie[23] observed a delay in the *a-c* interval, which was greatly increased by digitalis so that several ventricular beats dropped out altogether, and the pulse became markedly irregular. Stimulation of the vagus was also capable of converting delay of auriculoventricular conductivity into actual heart-block

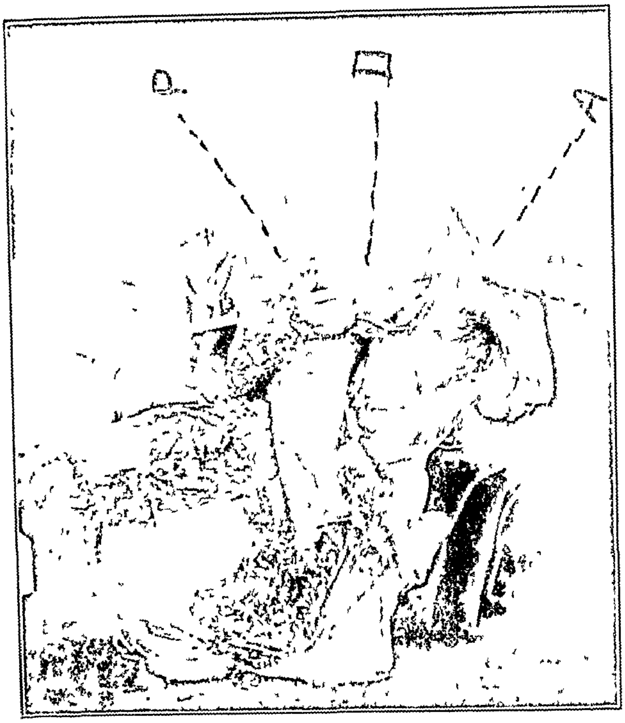

Fig 3—A, aorta: P, pulmonary artery; D, ductus arteriosus laid open, showing the opening into both the aorta and pulmonary artery

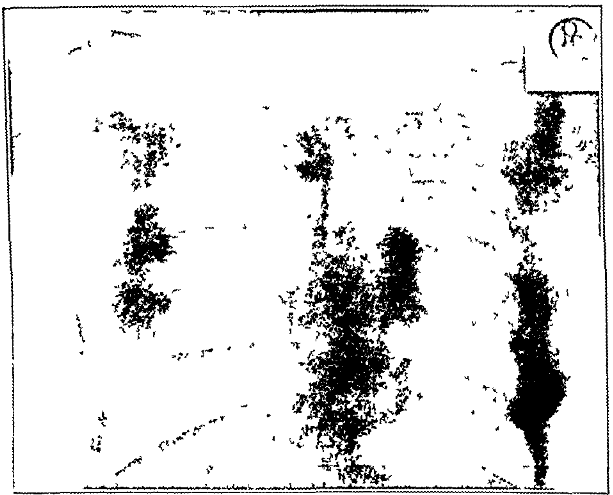

Fig 4—Radiograph taken by Dr Percy Brown, Boston, three months before the death of the patient

During all this time, despite the futility of treatment, the patient's color was very good. She was healthy looking, cheerful, interested in everything but herself, and never anxious as to her ultimate recovery, an optimism which was shared by all the consultants who examined her, as well as by me, up to the last thirty-six hours, when all the disagreeable symptoms rapidly increased, the most troublesome of all being the continuous laryngeal irritation, and which no hypodermics or any form of treatment could arrest until the final rupture of the heart and death.

The kidneys and liver shared in the general discomfort of this patient for the last two weeks of her life. The liver may be looked on as a sponge-like safety-valve to the heart, which works to its own destruction until edema and ascites occur. If death follows soon, the liver shows its engorgement; if death is postponed, the liver shrinks and shrivels. The edema and ascites in this case remained stationary, and the liver was not noticeably enlarged or fatty.

The condition of the kidneys and their function in this case is best described by Osler. "There is a great lessening in the total amount of urine excreted; darker color, strongly acid reaction which is caused by sarcolactic acid made from the poor arterial blood, and slight albumin." In other words, a mild nephritis, with thickening of the wall of the arteries such as was found at autopsy.

It is evident that we have one great lesson to learn from the history of such a case as this, namely, the necessity of early diagnosis of congenital defects in the heart, with consequent insistence on a hygienic life, protection as far as possible from infectious diseases (including rheumatism and common colds as well as influenza and children's diseases), and avoidance of nerve or muscle strain. Careful study of cardiac murmurs should teach us to know congenital anomalies, in order to differentiate them from endocardial inflammatory changes in the valves; and wherever it is possible, the diagnosis should be confirmed by autopsy and the cases studied and published for the benefit of the medical profession in the care of similar cases.

ABSTRACT OF DISCUSSION

Dr Wilder Tileston, New Haven, Conn.: I should like to emphasize the paralysis of the recurrent laryngeal nerve. Pressure by a dilated ductus arteriosus must now be added to the list of possible causes of recurrent laryngeal paralysis. A few years ago v Schroetter, jr, of Vienna, reported a case of patent ductus with laryngeal paralysis, exactly similar to Dr Mead's At that time this was the only case of the sort to be found in the literature.

SIMPLIFIED OPERATION FOR CHALAZIO

ROBERT SCOTT LAMB, M. D., WASHINGTON, D. C.

Ophthalmic surgeons have from time to time had recurrences after incising and curetting chalazia and I desire to call attention to a simple procedure which prevents the reforming of secretion in a not quite obliterated cyst wall. After anesthetizing the conjunctiva a chalazion forceps grasps the lid surrounding the tumor and the usual incision of the conjunctiva and the sac beneath is made at right angles to the lid margin. The contents are then carefully removed with a curette and the bleeding controlled A strabismus hook is then heated red over an alcohol flame, or an electric cautery point is used to gently touch the interior of the sac and so destroy the secreting surface. This has the obvious advantage over extirpation of simplifying the operation and the after treatment and of lessening the trauma. Previously I had used tincture of iodin, and at another period phenol, but nothing has been quite so satisfactory in my hands as the above procedure.

SODIUM CACODYLATE IN SYPHILIS

REPORT OF A CASE

A. J. CAFFREY, M.D.
MILWAUKEE, WIS.

History.—E. H., a young man, aged about 23, presented himself for treatment with a typical chancre on his lower lip. He gave a history of having a "cold sore" on his lip, and had become inoculated about a month or so before, by kissing. The disease is directly traceable to a woman who had syphilitic mucous patches on the inside of her lips. Dr. L. F. Jermain saw the patient also, and we made the diagnosis principally from the secondaries and the history of the case, examination for spirochetes not being deemed necessary.

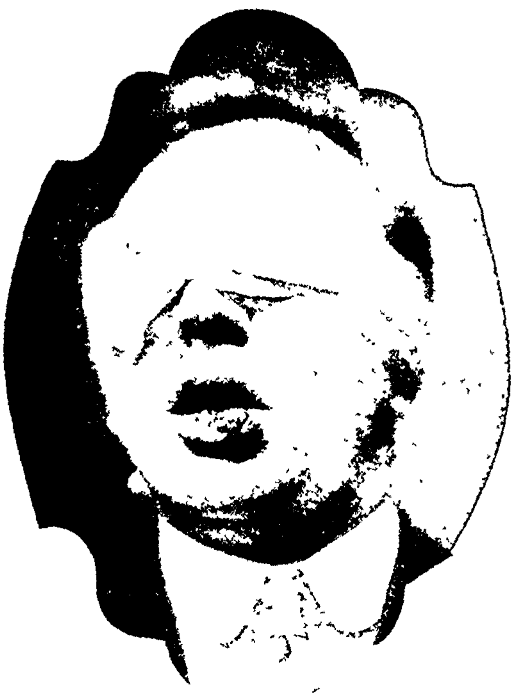

Fig. 1.—Chancre of lip at beginning of treatment with sodium cacodylate, Oct. 24, 1910.

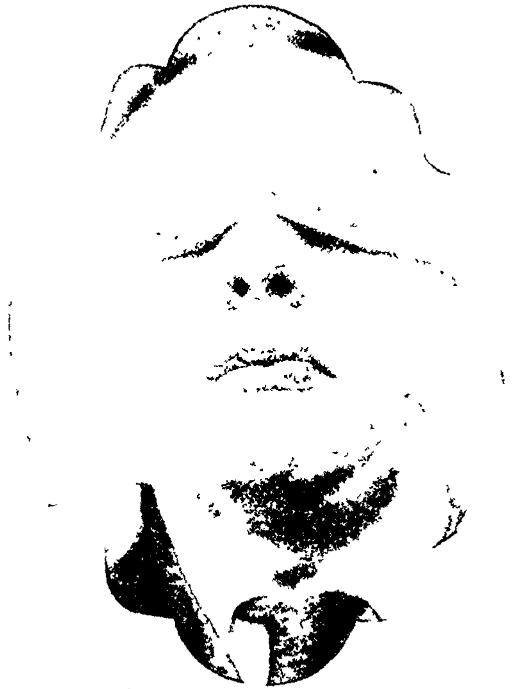

Fig. 2.—Soft, elevated, bleb-like condition, free from scab after fourteen days' treatment.

Examination.—The cervical and sublingual glands were swollen and nodular, and small papular eruptions were beginning to appear on the patient's face. He had received no treatment before he consulted me, which was on Oct. 24, 1910. The left tonsil was also swollen, as the photograph of October 24 shows.

Treatment.—I began October 24 giving one grain doses of sodium cacodylate by hypodermic injection into the pectoral muscles every twenty-four hours and continued this for eight days; then I doubled the dose for four days more. After the first dose, the pain and all the secondaries began to disappear, and at the end of twelve days all secondary manifestations had disappeared, but the chancre was not entirely healed; it was more circumscribed, however, and being afraid of the secondaries coming back, I consulted Dr. J. B. Murphy, who advised the injection of three grains daily for seven more days, which I did, with marvelous results. The scab cleared away like magic, and at the end of nineteen days' treatment all traces of the disease had left the patient, except a slightly elevated and indurated surface on the lip, which has since subsided and is forming a healthy scar under the influence of one grain doses of the drug given subcutaneously daily.

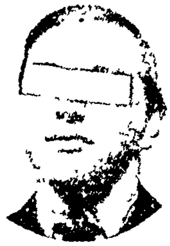

Fig. 3.—Beginning healthy scar; photograph taken Nov 20, 1910.

I treated this patient continuously from October 24 to November 20, as described above, excepting for two days while waiting to hear from Dr. Murphy. No other local or internal treatment was used. Of course time alone will tell whether the result is permanent, but I think the drug used is safe, because one can, as it were, feel one's way. I saw no disagreeable effects outside of a strong arsenical breath, which was so strong that one day the patient blew his breath on a fresh rose and it actually died inside of five minutes; this occurred at the end of a three-grain treatment. Physically the treatment had no ill effect on the patient, and he is now, as far as I can see, entirely cured.

600 Grand Avenue.

TRAPEZIUS TRANSPLANTATION IN THE TREATMENT OF DELTOID PARALYSIS

DEAN D. LEWIS, M.D.
CHICAGO

Although muscle and tendon transplantation has been used extensively during the past fifteen years to correct motor disturbances following paralysis of a muscle or group of muscles, but few cases are reported in which the procedure has been used to correct the motor disturbances associated with deltoid paralysis. Hoffa[1] reported three cases and Gersuny[2] one in 1906 in which the trapezius was transplanted into the paralyzed deltoid, and during the past year Kiliani[3] has reported another. The results in two of Hoffa's cases were very satisfactory. The third case could not be traced. In Gersuny's case the arm could be raised to the horizontal in four months and at the end of six months the range of motion approached the normal, but the movements were not carried out with much power. Kiliani's patient had a fair degree of motion after three months. Of the

Gersuny: Eine Operation bei motorischen Lähmungen, Wien. klin. Wchnschr., 1906, p. 263.

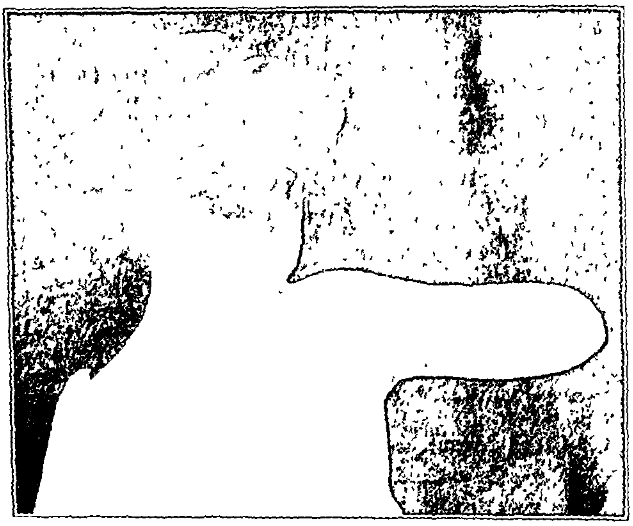
3. Kiliani, O. G. T.: An Operation for Paralytic Shoulder-Joint due to Infantile Paralysis, Ann. Surg., 1910, li, 79.

five patients operated on by transplantation of the trapezius into the deltoid, the results were highly satisfactory in four.

The object of this communication is to add reports of two cases to the five already published and to suggest a point in technic which, I believe, will prove to be of value.

The operation as originally practiced by Hoffa consisted of separating the clavicular, acromial and a portion of the spinous attachments of the trapezius muscle and of suturing the muscle which had been separated into the deltoid low down, the arm being held in extreme abduction. Gersuny practiced much the same procedure. He, however, chiselled up some bone with the trapezius, hoping that he might secure a better line of attachment by approximating this to the deltoid. Kiliani introduced two new points in the technic, (1) shortening of the capsule of the joint, and (2) plication of the long head of the biceps.

In both of the cases in which I have operated I have plicated the long head of the biceps without shortening the capsular ligament, and I believe this procedure is sufficient to overcome the pathologic subluxation in these cases.



Deltoid paralysis of nine years' standing following anterior poliomyelitis Power of abduction completely lost for nine years. Results eight weeks after transplantation of trapezius. The contracted outer border of the trapezius on the right side is prominent. History given under Case 2.

The results of the first case in which I operated were not entirely satisfactory. The imperfect result was due in part, I believe, to stretching of the paralyzed deltoid muscle.[4]

AUTHOR'S TECHNIC

In the second case the following technic was employed:

1. A longitudinal incision was made extending from the middle of the outer border of the trapezius muscle down to the junction of the middle with the lower third of the deltoid muscle.

2. The clavicular, acromial and a portion of the spinous attachments of the trapezius muscles were separated.

3. The atrophic deltoid was next separated from the clavicle and spine of the scapula and turned down.

4. The sheath of the long head of the biceps was opened, and the tendon, after being displaced from its bed, was plicated to correct the pathologic subluxation.

5. An attempt was then made to suture the trapezius low down on the humerus. This was impossible, because the spinal accessory nerve interfered. *The trapezius was then sutured* into the capsule, where it is attached to the humerus. I believe that the suture of the trapezius *into* the capsule at its attachment to the humerus is an important point. If it were possible, it would be better to suture the muscle directly into the bone lower down, but the spinal accessory nerve becomes so tense that its function would be interfered with if the attempt were made. The trapezius can easily be sutured at the line just mentioned, and apparently this attachment affords sufficient purchase to carry out the movements which follow contraction of the muscle.

6. The deltoid was then sutured over the trapezius high up, the arm being held in hyperabduction.

7. The upper part of the skin suture was sutured transversely, with the idea that shortening the skin incision in this way might aid in overcoming the pathologic subluxation. The incision when completed resembled the letter T, the *horizontal* arm of the T extending across the summit of the shoulder.

The arm was then dressed at an angle of about 100 degrees, and maintained in this position for about four and one-half weeks. Then it was gradually lowered.

The results at the end of eight weeks are shown in the accompanying illustration. The patient raises the right arm, the forearm being flexed, quite rapidly to the horizontal, but she cannot hold the arm in this position for any great length of time. The movements are carried out with precision and power. The outer edge of the contracted trapezius can be seen in the illustration. No contraction of the deltoid takes place. The pathologic subluxation has been overcome and the appearance of the shoulder has been improved, as it now has a rounded contour. There had been complete loss of abduction in this case for nine years. Paralysis of the deltoid was apparently due to anterior poliomyelitis.

The following are the histories of the two cases:

Case 1.—*History.*—Mr. E. B., aged 25, was referred to me Jan. 17. 1910, by Dr. Thor Rothstein, who suggested that the trapezius muscle be used to correct the effects of the deltoid paralysis. Two years previously, the patient had fallen into a pit and had injured his chest and left shoulder. He soon went back to work, but was *unable* to use the left arm as he did before the injury. About two weeks after the accident, he was taken sick, with high fever, nausea and vomiting, headache and pain in the muscles of the neck. After about thirty-six hours the left upper extremity was almost completely paralyzed.

Examination.—The left upper extremity hung perfectly limp. The muscles about the shoulder were flattened and atrophic. The supraspinous and infraspinous *fossæ* were sunken; the acromion process was prominent and the head of the humerus was displaced downward and forward: two fingers could be placed in the groove between the acromion and the head of the humerus. The forearm could not be flexed and the muscles on the anterior surface of the arm were atrophic; the biceps and brachialis anticus were paralyzed. There was some pronation, but both pronation and supination were seriously *interfered* with. The fingers were partially flexed in a position *somewhat* suggestive of claw-hand and the interossei muscles were atrophic. Sensation in the entire extremity was somewhat impaired. The patient had no motion in the *upper extremity*, except a peculiar swinging movement, *which occurred* when he swayed the entire body.

Operative Results.—These were not altogether satisfactory. The pathologic dislocation was *corrected*; there was some abduction of the arm, but the *improvement* did not permit any great range of motion. The failure was in part due, I believe, *to* the lengthening of the paralyzed deltoid muscle, on which depended the transmission of power obtained by transplantation of the trapezius.

---

[4] Bradford, in the August number of the American Journal of Orthopedic Surgery, reports seven cases of deltoid paralysis treated by the periosteal silk strand transfer method. The results were satisfactory. He believes that this method does away with the possibility of stretching of either the transplanted or paralyzed muscle.

Case 2.—*History.*—Miss K., aged 18, up to the age of 9, had had full use of the right arm. At this time she fell from a fence, a distance of about 4 feet, and struck on the summit of the shoulder. Immediately following the fall there was some loss of function, but this, as the patient stated, was due to local tenderness about the shoulder. Following the fall, the patient was sick in bed for about two weeks. She could not state the nature of her illness, but at the end of one week there developed, quite suddenly, paralysis of some of the muscles about the shoulder. This was evidently a case of cervical poliomyelitis, although the history is somewhat suggestive of an ascending neuritis of the axillary nerve.

Examination.—The right arm hung limp. The shoulder was flattened, the head of the humerus was displaced downward, so that a finger could be placed in the groove between it and the acromion. The supraspinous and infraspinous fossæ were full, but rotation was somewhat interfered with. The latissimus dorsi was somewhat atrophic. There were no sensory disturbances. The muscles of the arm were well developed, but flexion of the forearm was nót as strong as on the opposite side.

Operative Results.—The trapezius was transplanted as described, and at the end of eight weeks the arm could be raised to the horizontal, as indicated in the figure.

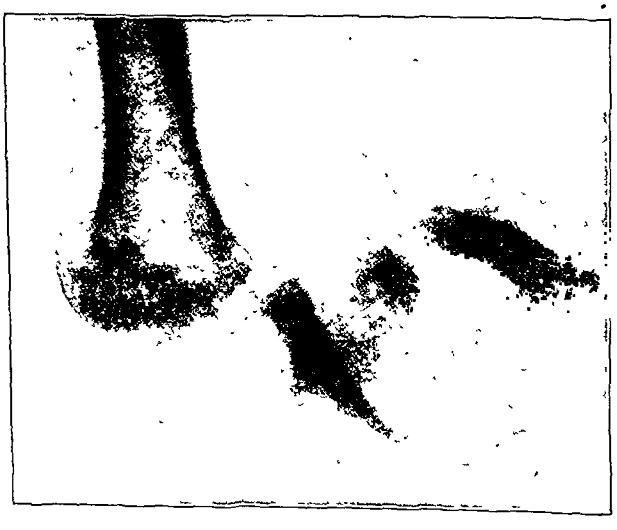
CONGENITAL DISLOCATION OF THE SHOULDER-JOINT

VICTOR F. HUNTLEY, M.D.
MANTON, MICH.

The skiagram shown here was taken during some experimental work on the chest, in an effort to demonstrate early tuberculosis. The case appeared to me to be so unusual at least, that I thought it might prove of interest to the many readers of The Journal; hence this report:

The case is that of a young man aged about 30, who has always been able by raising the arms above the head to produce a complete dislocation of the head of the humerus; the dislocation being downward and outward as is well portrayed by the skiagram. This anomalous condition causes no discomfort, as his occupation does not require any considerable employment of his arms in an overhead position, and the head of the humerus immediately resumes its proper place when the arms are in their resting position, the excursion of the head apparently causing no irritation of the surrounding ligaments and muscles.



Skiagram showing congenital dislocation of the shoulder-joint.

The point of particular interest, to myself at least, in this case is the position of the spine of the scapula and the apparent open space between or at the junction of the clavicle and the acromion process of the scapular spine. The skiagram was taken with the patient lying on his back on the table, arm drawn up and flexed at the elbow with the hand under the head. The extreme mobility of the scapula is well shown in the skiagram as well as the marvelous flexibility of the scapula and clavicle in the upward movement of the arm. The apparent break in the epiphysis is no doubt more apparent than real, the rays undoubtedly passing through the more porous texture of the bone. It serves to show the junction of the bones very clearly, and their relation to the coracoid process is also well developed while in this exaggerated position, and it brings out with great satisfaction the wonderfully flexible bony protection to this greatest of all joints, the human shoulder.

SPOROTRICHOSIS IN AMERICA

RICHARD L. SUTTON, M.D.
KANSAS CITY, MO.

Since the publication of my recent article on sporotrichosis,[1] I have received communications from several physicians regarding similar cases which they have encountered in their work. Although cultures were made in only a few instances, the clinical manifestations in the majority of the cases were such that there can be little doubt regarding the nature of the causative agent. Four other American cases have been reported since my article was written, one by Stelwagon,[2] one by Pusey,[3] and one by Hyde and Davis[4] (who refer to a third Chicago case under the care of Dr. Zuraski).

Pusey has suggested that the affection probably occurs much more frequently than statistics would indicate, and my experience certainly tends to prove the correctness of this supposition. The lesions often resemble those of tertiary lues, and as they heal promptly under antisyphilitic treatment it is very probable that many cases of sporotrichosis have been incorrectly diagnosed, but successfully treated, as instances of gumma. When the characteristic symptomatology of the affection is borne in mind, however, this mistake is not liable to occur.

A traumatic lesion of the hand, forearm, or leg which proves resistant to ordinary surgical treatment, and is accompanied by the development of one or more sharply circumscribed, painless, cutaneous or subcutaneous abscesses along the course of the limb, should always arouse suspicion, especially if the inflammatory manifestations typical of a streptococcic cellulitis are absent. A microscopic examination of the contents of the abscesses is usually negative, although the organism multiplies readily on agar and other simple culture media.

In France it has been found that the disease occurs more frequently in the rural districts than in the cities (owing to the fact that the sporothrix thrives best on vegetable matter, thus affording abundant opportunity for the infection of slight open wounds on the hands and arms of farmers and others of similar occupation).

[4] Hyde and Davis: Jour. Cutan. Dis., xxviii, 321.

Since sporotrichosis in man is comparatively rare in America, the two following cases of the disease, and one of syphilis simulating sporotrichosis, are of interest.

Case 1.—This occurred in the practice of Dr. Ira B. Chadwick of Tyro, Kan. I am indebted to Dr. Howard Hill of this city for a photograph of the affected limb (Fig. 1), and for other courtesies. The history, taken by Dr. Chadwick, follows. The patient, A. B., was a farmer's boy, aged 11, a native of Missouri, and a resident of Kansas. The cutaneous history of the family is negative. The lesion developed from a hen bite on the back of the right hand. The wound had ulcerated under home treatment, and when first seen by the physician was oval in shape, with a raised border, and about the size of a silver dollar. Abscesses began to form on the forearm about four weeks after the injury was received. In the course of two months twenty-one abscesses developed. These were opened, treated with antiseptics, and later excised completely. At no time was there any glandular enlargement. The abscesses were confined to the arm, no other part of the body being affected. A number of microscopic examinations of the contents of the abscesses were made (methylene blue, Wright's, and carbol-fuchsin being used), but no micro-organisms were found. The pus resembled "thickened cocoanut milk." None of the incised lesions showed a tendency to heal, and recovery took place only after the entire wall of each abscess had been dissected out. Dr. Chadwick was repeatedly advised by other physicians to amputate the limb, but refused to do so. The patient was discharged cured at the end of ten weeks. Considerable scarring remains, but the patient retains perfect use of his arm.

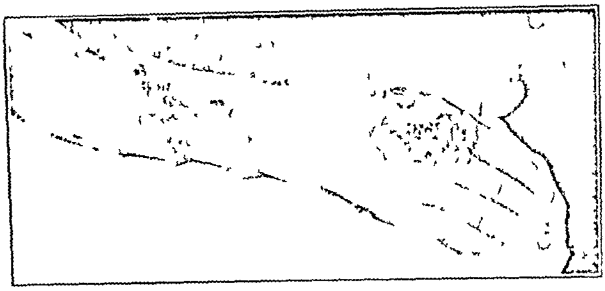

Fig. 1.—Wound on dorsum of hand with typical chain of abscesses extending up the forearm (Case 1).

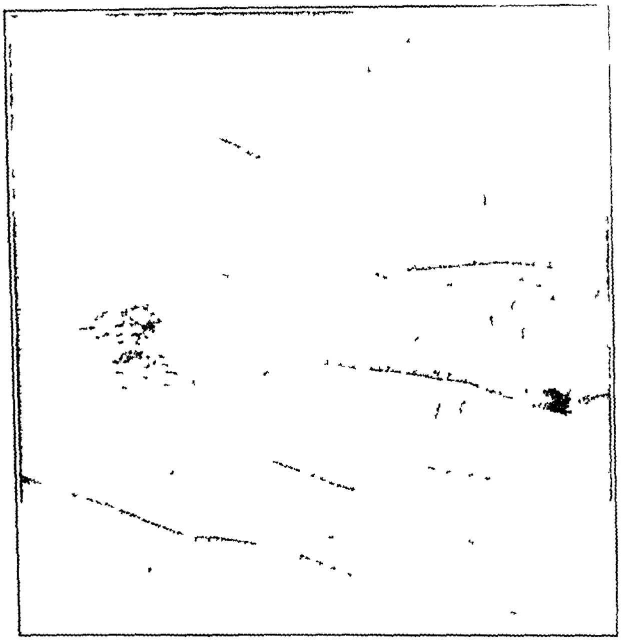

Fig. 2.—Site of original wound (3 months after injury was received) in Case 2.

Case 2.—This occurred in the practice of Dr. N. P. Wood of Independence, Mo. The cultures were made and the etiologic organisms isolated by Dr. Frank J. Hall of this city, to whom I am indebted for the case history and for the photograph (taken by Dr. Hall's associate, Dr. O. L. Castle). The patient, L. M., was a farmer's daughter, aged 18, a native of Kansas and a resident of Missouri. The cutaneous history of the family is negative. The lesion developed from a slight wound on the back of the right hand, the patient having accidentally injured herself while feeding Kaffir corn to domestic animals. At the time the photograph was taken (Fig. 2) the lesion had been present three months. Two small, subcutaneous abscesses were present, one just above the annular ligament and one midway between the wrist and elbow. The sporotrichosis (Schenck) was secured in pure culture from one of the abscesses. All of the lesions healed promptly under the administration of potassium iodid.

Case 3.—This occurred in the practice of Dr. C. D. Osborne of Highpoint, Mo. The patient, R. S., a farmer's daughter, aged 16, a native of Missouri and a resident of Moniteau County, Mo. Two months prior to the date on which the patient consulted Dr. Osborne, she had received a slight incised wound on the ball of the index-finger of the right hand while manipulating a kraut-cutter. The lesion refused to heal, in spite of the application of spirits of turpentine and various other household remedies. At the time of the examination this lesion was about the size of a dime, and was partially covered with a layer of disintegrated epidermis and stringy, adherent pus. Beneath this coating were masses of exuberant granulation tissue which bled easily, but were not painful to the touch. The surrounding skin was undermined with pus, but there was no areola of hyperemia. Extending up the ulnar side of the forearm and the inner side of the upper arm was a chain of cutaneous and subcutaneous abscesses, eleven in number. Two of these, both located near the wrist, had ulcerated through the epidermis and thick, brownish pus exuded when pressure was applied over the lesions. There was present no evidence of a coccic cellulitis, the glands were not involved, and there was practically no pain. Only the right hand and arm were affected. After employing antiseptics for a few days, Dr. Osborne concluded that the case was an unusual one of syphilis and placed the patient on mixed treatment. The lesions slowly healed, in the course of four or five weeks, leaving slight scars.

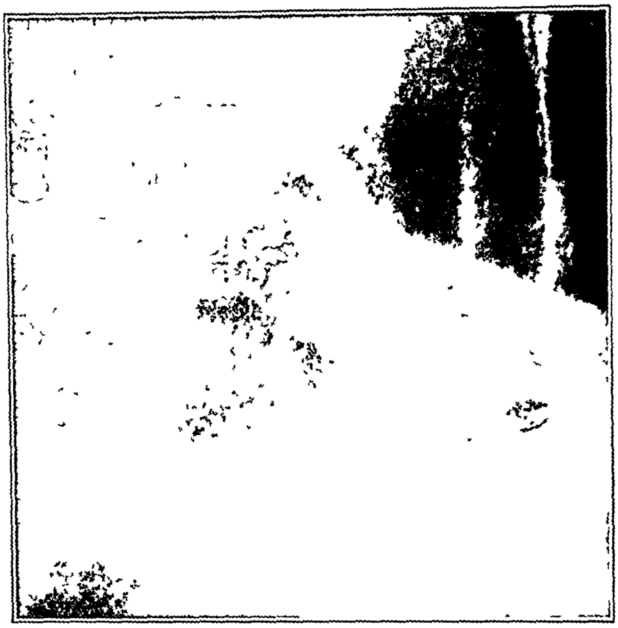

Fig. 3.—Ulcerated gummata (syphilitic) resembling the ulcers sometimes seen in sporotrichosis. The lesions are irregularly grouped, however, and considerably indurated.

CONSERVATIVE SURGERY OF THE PELVIC ORGANS AND THE LOWER ABDOMINAL WALL *

FLOYD W. McRAE, M.D.
ATLANTA, GA.

It is not my purpose to attempt to present anything new, but rather to discuss end-results in pelvic surgery from the viewpoint of a practical man who has kept in exceptionally close touch with his cases, prior to and following surgical operations.

For fourteen years I did a very active general practice with a constantly increasing surgical element. For ten years now, I have limited my work to surgery and surgical consultations.

I reside within 200 miles of where I was born in a community of Scotch settlers as clannish as native Scots; I am of Scotch extraction, a member of perhaps the most prolific and ramifying family of all those Scotch pioneers. A great deal of my surgery has been done on these relatives and life-time friends, thus enabling me to follow up my cases.

Atlanta has been the field of my professional activities, her population nearly trebling during my residence there. As a general practitioner doing surgery, I knew intimately postsurgical results. I simply state these facts as explanatory.

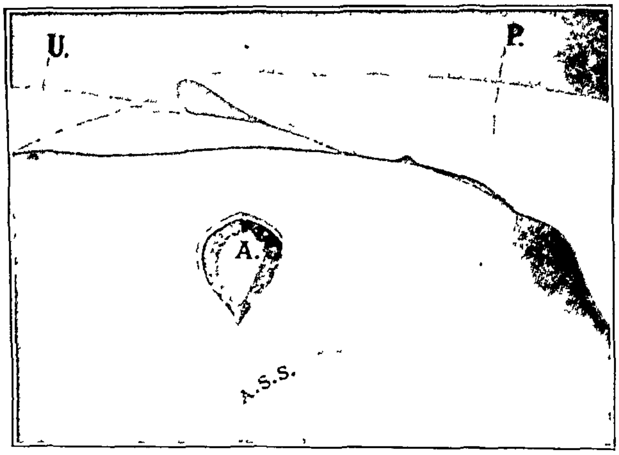

Fig. 1.—Initial incision in author's operation for appendicitis A, aponeurosis; U, umbilicus; P, pubes; A. S S, anterior superior spine

On account of these unusual relations, I have been intensely sympathetic and individual in my surgery, forgetting sometimes, I fear, the general good of surgery, in the (to me) all-absorbing problems of the case in hand. What will enhance this individual's chances for recovery? What will promote his or her permanent, complete restoration to health and comfort? In this intensely personal application of surgery, I may have unwittingly failed in a measure to bear in mind always that obverse of the picture—the greatest good to the largest number.

Thus following up closely and keeping in touch with my postoperative cases, I have not infrequently been chagrined to find that while the surgical procedures were "successful," the patients were not cured; or there were sequelæ quite as disabling, often more disquieting, than the conditions for which the operations were done. This has been notably true of complete oophorectomies and complete salpingo-oophorectomies.

We have only to review our pelvic surgery—to follow up our cases—to find many instances in which surgery has proved harmful rather than helpful. This is not really the fault of surgery or of surgeons. New procedures must be worked out carefully, followed up conscientiously, and reports of results made faithfully, that we may know *just what to expect.*

The Battey and Tait operations, championed by many of the most brilliant and esteemed abdominal surgeons, initiated a "furor operativus" that cost hundreds of thousands of women their ovaries with the consequent disabilities and neuroses that so frequently follow oophorectomy. How many homes have thus been rendered childless, loveless and broken up by our former lack of knowledge of the internal secretions of these organs! My first laparotomy was done for tender, cystic ovaries, which I removed successfully, but with infinite disaster to my patient. Poor creature! For nearly twenty years I watched her wasting life. During this whole time she was a loyal patient. I did everything I knew; referred her to all kinds of specialists, only to get her back with that appealing look for help. She died eventually with cancer of the uterus. What influence, if any, my operation on her two decades ago,

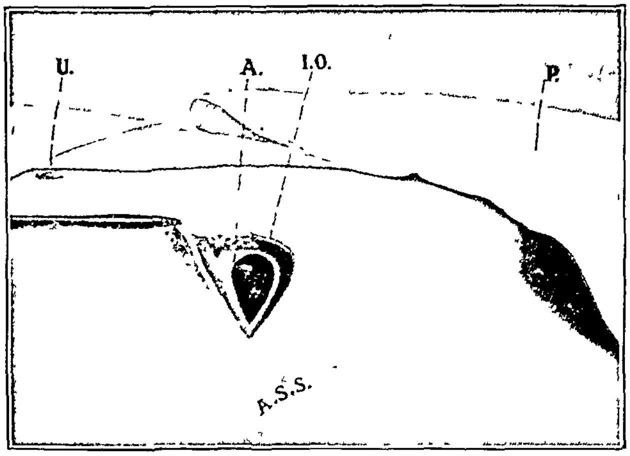

Fig 2.—Second step in author's operation I O, internal oblique muscle. Other lettering same as in Figure 1

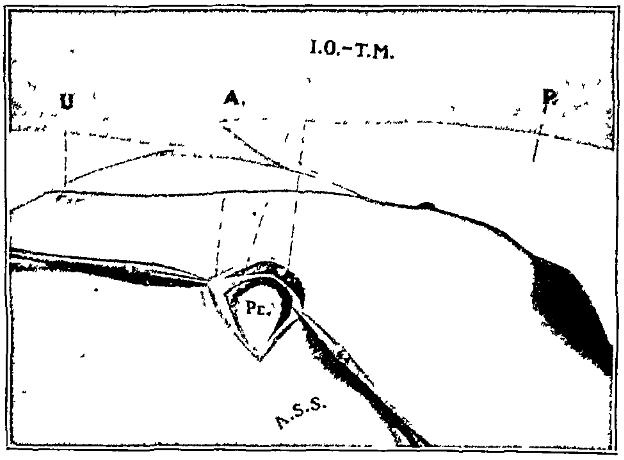

Fig 3.—Third step I. O-T. M., internal oblique and transversalis muscles, separated and retracted; Pe., peritoneum Other lettering same as in Figure 2.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

which made her miserable, bore on her as an etiologic factor of her fatal disease, I do not know. But of one thing I am sure, and that is that if I had been more conservative her resisting powers would not have been lowered.

I shall deal with the subject of conservative surgery from an individual rather than from a collective standpoint.

Every patient submitting his or her case to the surgeon (in the absence of urgent necessity for immediate operation), has the right to expect and should receive an exhaustive examination for diagnosis, and thereupon a mature prognosis after a carefully considered detailed history.

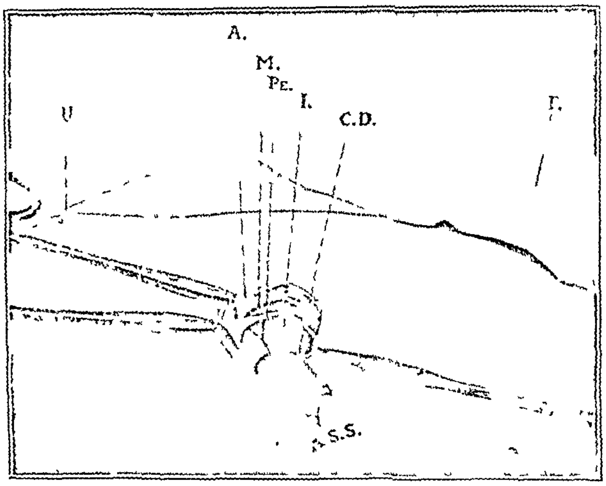

Fig 4.—Fourth step Cigaret drain (C D) inserted in outer angle of wound M, muscles separated and retracted; I, intestine Other lettering same as before

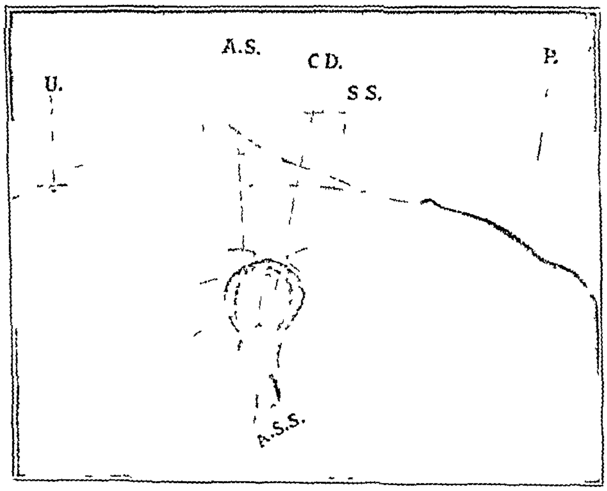

Fig 5.—Fifth step A S, aponeurosis sutured; S S, silkworm gut sutures Other lettering as before

It is quite too much the vogue for operating surgeons, after a desultory history and hurried examination to make some such remark in the operating-room as—"there is something wrong in this abdomen. I will tell you what it is after I open up and see inside." Such remarks have a bad influence on medical students and young surgeons, tending to the far-too-prevalent practice of rushing patients to the operating-table to be opened up for general results. The general practitioner finds many of these patients returned to him surgical victims rather than surgical victories. Such work excused, if it did not warrant, the epigram, "furor operativus," made by a brilliant, lamented surgeon of international reputation in his presidential address before the last Atlanta meeting of the American Medical Association. Such work, in a measure, justifies the feeling on the part of some internists that they must stand between their patients and operating surgeons. We should not be satisfied to have our patients simply recover from operations. Surgery that does not benefit or cure the patient is harmful, lessening confidence in surgery and surgeons, and often deterring those with serious surgical conditions from submitting to necessary operations.

By conservative surgery I mean that type of surgery that aims at conserving tissues and functionating organs in whole or in part, when this can be done without undue harm to the life of the individual.

Considering the subject as a whole, radical surgery is frequently the most conservative surgery. No surgeon could possibly believe more firmly, nor advise more earnestly, than do I, prompt interference in acute appendicitis, acute obstruction of the bowels, perforation of the alimentary tract, penetrating wounds of the abdomen, etc. Delays under these, or like tragic conditions, to make hair-splitting diagnoses, are little short of criminal. Here it is the surgeon's duty, as stated by a distinguished southern surgeon, to "get into the abdomen as quickly as possible, do the essential work, and get out of the abdomen as quickly as possible." Where, however, there is nothing urgent, failure to consider seriously the individual from every viewpoint is equally reprehensible.

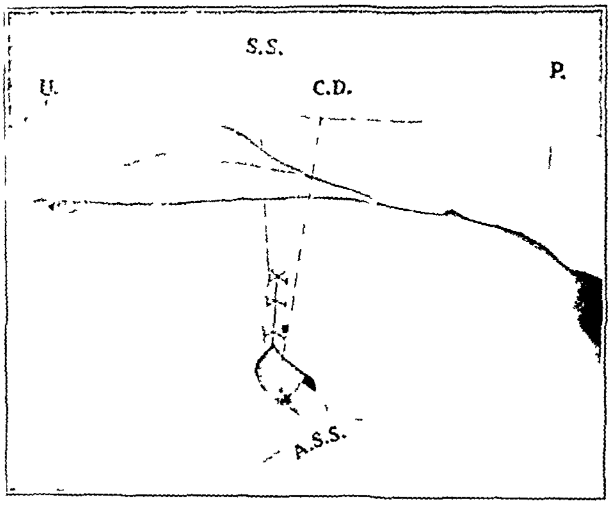

Fig 6.—Operation completed Silkworm gut sutures tied.

Neuroses, intestinal toxemias and parasites, visceral ptoses, as well as heart, lung and kidney conditions, should all receive careful consideration and be given due weight. *Repeated examinations* of the urine, examination of the stomach contents and feces, examination of the blood, x-ray examinations covering a period of from two to ten days, should be made. Two days may be sufficient; ten days is a period none too long to keep some of these patients under observation and treatment before resorting to surgery. In doubtful complicated conditions even weeks of observation may be necessary. Thus by a systematic plan of coordination and elimination, we may arrive at far more accurate diagnoses and give better advice as to treatment.

I began doing conservative work on the ovaries and tubes in September, 1903, impressed by the many hopeless and helpless wrecks following my own complete salpingo-oophorectomies, and similar wrecks following like operations done by other surgeons and gynecologists which came under my observation. At that time no conservative work was being done in Grady Hospital, our large city hospital, nor was there, so far as I was then aware, any being done in my vicinity. Prolapsed ovaries, cystic ovaries, were removed with their tubes. In acute pelvic infections and pus cases, the tubes and ovaries were also completely removed. Hysterectomies were frequently done in addition.

I have been largely influenced to bring these subjects before this Section for discussion by the recent articles on conservative surgery of the ovaries by Dr. J. O. Polak,[1] of New York, Dr. R. A. Barr, Nashville, Tenn., and Dr. James W. Cokenower, of Des Moines, Iowa, all of whom practically condemn conservative surgery of the ovaries and tubes. Their reasons as given are: fewer immediate cures, the large number of patients returning later for radical operations, after conservative operations have failed. The small percentage (5 per cent. to 10 per cent.) of women bearing children after conservative operations, seems, however, to be their chief argument.

My own experience differs materially from the experiences of these gentlemen in every particular. My observation of several hundred complete operations done in hospital and private practice, and later personal experience with 135 conservative operations on the ovaries and tubes, has satisfied me that the number of complete and satisfactory cures is larger following the conservative operation than following radical procedures. Some of the patients on whom conservative operations have been done return for later operations, conservative or radical, as indicated; just as many patients on whom radical operations have been done return later for the breaking up of adhesions, partial or complete intestinal obstruction, etc.

My conservative operations in married women have been followed by a fraction less than 16 per cent. of known pregnancies and safe deliveries of healthy children. I do not doubt that some of those who have passed from under my observation have also borne children. Most of my conservative operations, however, have been done on young women, and here I think the results have been even better than in married women. Artificial menopause has been prevented, the natural characteristics of the woman have also been preserved; they have retained their womanly traits and their womanliness. They have been preserved from that feeling of being set apart from their kind which comes to most of the women that I have known on whom radical operations have been done. I may have been peculiarly unfortunate in having these poor creatures appeal to me so frequently for help; but my inquiries among general practitioners, gynecologists, and neurologists, have confirmed my own experience. Almost without exception my own observation is confirmed by the general practitioners and female gynecologists, who have large opportunities for observation and intimate knowledge of these cases, making their observation especially valuable; and neurologists to whom these miserable creatures are referred as a last resort, to eke out their remaining days in abject suffering, despondency and disappointment. I have discussed this subject freely with Dr. Sawyer, our leading woman gynecologist and obstetrician, and have her consent to quote her experience, with reports of typical cases. I have also talked the matter over frequently and in detail with Dr. E. Bates Block, our leading neurologist, and his experience coincides almost exactly with that expresed above.

The argument that only 5 to 10 per cent. of pregnancies follow conservative operations, and therefore these operations should be condemned, seems to me to be not well supported, or based on sound fundamental facts and reasoning. When we consider the thousands and thousands of radical operations that have been done during the last twenty-five years, and the ever-increasing tendency towards race suicide, even this small percentage of homes preserved and children borne is no small argument.

As we work out these conservative operations more in detail, with better technic, a larger and larger percentage of pregnancies will follow.

There must always be a great difference between the results obtained in private practice amongst the better classes of people and the results obtained in large charity hospitals. A large percentage of these latter cases cannot be followed up, and their subsequent histories as to operations and pregnancies cannot be gathered with any degree of accuracy.

I am constrained to insert here the report of five cases from the pen of a woman physician, who was a nurse before she studied medicine. She says:

> Than that of the poor, miserable woman, undergoing the nervous changes following the entire removal of both ovaries, there can be, to me, no sadder state in life. An observation of these cases covering some seventeen years, many of them women whom I had known prior to operation, convinces me that their last state is worse than their first.
>
> Reviewing the history of a number of these women, who, in a vain hope of finding some relief, have sought me, I find the invariable and most marked symptom is that of despondency; sooner or later the feeling of utter hopelessness is theirs. Restlessness, discontent, inability to engage in former duties or pleasures, bitterness and fear of the future, together with loss of power to control the emotions, are always present. A scene of weeping is a part of every interview. The physical findings vary only slightly—a narrow vagina (frequently it is with difficulty that I introduce the examining finger, even in those who have borne children), a small cervix, which bleeds on the slightest touch, as does the vaginal mucosa; the uterine body is small and exquisitely tender. These examinations are always made with difficulty, provoking the most exaggerated nervous manifestations.
>
> Case 1.—Miss M., aged 22, on whom I saw the operation done in January, 1895, came to me in the spring of 1904, nine years afterwards, with an appeal to do something to help the "unbearable nervousness" from which she suffered. She was despondent and altogether miserable. Her home life, she admitted, was all that it could be to make one happy, but she took no enjoyment in it. Examination showed the typical condition described.
>
> Case 2.—Miss B., aged 21, operated on in September, 1896, of a cheerful, happy disposition, as I remembered her in girlhood, was so changed, when I again saw her in 1905, that I would not have recognized her as the same. She expressed herself as never having had one moment's freedom from pain and nervousness since the operation; she wished that she had died at the time. She had consulted various specialists, North and South, with no assurances of relief by operation or treatment. Examination showed the vagina so contracted that it was almost impossible to introduce the index-finger, a diminutive uterus so tender as to cause an outcry of pain on the slightest touch, and profuse bleeding from the gentlest manip-

---

[1] Polak, John Osborn: Final Results in Conservative Surgery on the Ovaries, The Journal A. M. A., Oct. 22, 1909, p. 1382.

ulation. She is now a hopeless wreck, with the bitterest condemnation of the surgeon who did the operation.

Case 3.—Mrs. C. had a double ovariotomy nine years previous to consulting me. At no time since the operation had she been so well as before, and at the time that I saw her she was a bed-ridden invalid. She complained of pain in every part of the body (with no disease of any organ that I could find), of wretchedness and despair. The trend was a lament that she was a burden to her husband and family, and wished she were dead. The atrophic vaginal and uterine changes were most marked. She underwent an operation some months ago for what the surgeon termed "adhesions," but says she is in no way benefited by it.

Case 4.—Mrs. H., with a history of an operation done twelve years ago, presented herself, with symptoms similar to those of Mrs. C. She was a woman of unusual strength of character; her effort to overcome the train of nervous symptoms which have followed the operation has been of the strongest. She views the future without hope, but is trying to make the best of an empty life. And so I might tabulate the entire list, finding only the slightest variation in phases of nervousness or physical signs.

Surely these victims of mistaken judgment should invite a plea for conservative surgery on the ovary.

AUTHOR'S INCISION IN APPENDICITIS

Let me now direct your attention to my method of opening the abdomen for appendicitis, simply to place it on record. The hernias following late operations for acute suppurating and fulminant appendicitis are disabling, sometimes dangerous, and usually preventable.

May 10, 1903, in my one hundred and twelfth operation for appendicitis, I made my first transverse cut to reach a gangrenous appendix. It then seemed to me that such a cut would give better exposure, better drainage, less trauma, and leave the abdominal wall far less liable to subsequent hernial development. An experience covering seventy-six cases in late, neglected, acute appendiceal abscesses, in perforative and fulminant appendicitis, many with advanced spreading peritonitis, has abundantly demonstrated the feasibility of the operation, and has proved it to be the best incision in my hands for such cases. I do not advocate this incision in cases suitable for the McBurney gridiron operation. or those associated with pelvic pathologic conditions that should be dealt with at the same time.

I make a transverse cut well out in the flank through the skin and superficial fascia, buttonholing the aponeurosis; then separating the transverse fibers of the internal oblique and transversalis muscles I next make a transverse cut through the transversalis fascia and peritoneum. This incision, if made well to the outside, gives the very best possible drainage outlet in appendiceal cases. It is easily retracted, giving much more room and better exposure than does a lateral incision to the outside of. or through, the fibers of the right rectus muscle. While there is a direct opening through the whole abdominal wall, two muscle layers, the internal oblique and transversalis, are practically uninjured, the nerve and blood-supply little interfered with. lessening also the danger of inguinal hernia. Where complications are encountered, and still more room is needed, the incision may be extended to the median line, through the skin and superficial fascia, the internal oblique and transversalis muscles separated to the edge of the rectus, the sheath of the rectus cut transversely and the edge of that muscle lifted up. The posterior sheath may also be cut if necessary. The advantages of the operation are: facility, better drainage, better exposure, protection against ventral hernia, and less danger of inguinal hernia following.

I have followed up many of my transverse operations, and in all of the cases observed have found a good solid scar. Certainly some hernias will result. That I do not advocate or employ the transverse incision as a routine, is evidenced by the fact that I have performed this operation only 76 times in the last 567 appendectomies.

ABSTRACT OF DISCUSSION

Dr. **Alexander Hugh Ferguson**, Chicago: The end-result of operating on prolapsed ovaries and on small cysts in the ovaries has, no doubt, been pretty well decided in the experience of almost every surgeon of note. This work does not entirely belong to the gynecologist: surgeons deserve a great deal of credit. I have not for its own sake removed a prolapsed ovary in twenty years. I have removed small and large cysts from ovaries in hundreds of cases, but I have always conserved all the ovarian tissue I could, just as Dr. McRae has. I have done this not merely to favor the propagation of the race, but to maintain the mental equilibrium and happiness of the patient. These cases can be divided into two classes. First, there are the patients who are not nervous primarily, but who have cystic and prolapsed ovaries. One cannot class them with the neurotics; however, if allowed to continue in that state they will become nervous. If those ovaries and tubes are removed simply because they are displaced and a little cystic, these patients can be converted into hopeless neurasthenics. Then there is a second class that comes before us prominently to-day. What shall we do with a neurasthenic patient who is suffering with pelvic tenderness, due to prolapse, uterine disease or cystic ovaries? Shall we operate on these patients? Why not? If we do not operate the condition becomes profound and the patient may become insane. The majority become invalids. If we remove the pathologic condition from the pelvis, we remove a certain amount of the irritation that was interfering with the well-being of the patient or that caused the displacement of the ovary, etc. Shortening the ligaments, removing the cysts and making the pelvis as nearly normal as possible, will not interfere with the nerves of the patient, nor with her mentality. Some surgeons have stated that no operation should be done on a neurasthenic. That is a mistake. Even the insane claim our honest attention, and removal of diseased tissues will often better the patient's mental condition. Then we come to the very acute cases, in which surgery has not often been practiced. A young woman became pregnant, and fearing discovery, because she had been married secretly, she went to an abortionist. She developed acute pyosalpinx, with a temperature of 105 F, I opened the Douglas' cul-de-sac and found pus there and also a double pyosalpinx. I then opened the abdomen and found the appendix involved secondarily. What would you do? Ablate these tubes? No! I split the fundus of the uterus transversely and drained the pus into the uterus. The fimbriated ends of the tubes were opened. In five weeks this young woman left the hospital apparently in an excellent condition.

Dr. **J. M. Baldy**, Philadelphia: It seems a pity that surgeons should go to the extreme on any surgical subject in this day, and especially when it is a question of pelvic surgery, pure and simple. To acknowledge oneself as always doing conservative surgery or as always doing radical surgery, is a tacit acknowledgement of mental immaturity. A great deal is said about conserving the pelvic organs, and much is said about complete hysterectomy and the removal of everything, but very little is said about a very essential feature, one regarding which all thorough surgeons and gynecologists agree, and that is to make a proper diagnosis, and to know beforehand whether any operation should be done. Therein lies the great evil, the great harm of all this work. More patients are injured, not because they have the ovaries and tubes removed, or because any conservative surgery is done, but because they were operated on at all when operation was not indicated. They were simply neurasthenics, patients who belonged to the neurologist, who needed common-sense, outdoor life, or anything else you choose, except to fall into the hands of the surgeon. That is a lesson everyone of us must learn. It is a fact that where you find a young community of young surgeons, that is, surgeons young in surgery, and where you find that other class of men, the so-called general surgeons, men who dabble in everything—surgery, gynecology and what not, you will find that many unnecessary operations are done; that is, many patients are operated on when what they really need is medical care.

Dr. Hyman M. Folkes, Biloxi, Miss.: The diagnosis is the essential feature in these cases. As Dr. Baldy well put it, every sensible man, every man of large experience, will know when to operate and what to do after he has entered the abdominal cavity. Practically 50 per cent. of these cases are not operative cases. Dr. McRae brought out a point that few surgeons have realized to any great extent, and that is the end-results of injudicious surgical procedures. I have had many patients who have been operated on times without number. I remember one woman, aged 30, who had been subjected to sixteen operations, and she was in as bad a condition after the sixteenth operation as she was before the first, if not worse. The younger these women are when they are robbed of their ovaries, the worse off they are in every respect; I mean women who are operated on injudiciously. Every sensible person knows that when there exists in the abdomen any condition requiring radical surgery, it should be done, regardless of end-results. One cannot stop to consider the patient from the neurologic standpoint; she must be considered from the surgical standpoint exclusively. I recall a young woman of 20, who had both ovaries removed at the age of 18, and every 20 or 30 days she had the most distressing symptoms. The urine output was as low as 6 ounces for the 24 hours, and the girl was almost blind. There was at no time any condition like nephritis. Except for the reduced quantity, the urine was entirely negative, so far as any involvement of the kidneys was concerned. I could not regard the case as anything other than a toxemia. Relative to these end-results, I have consulted many gynecologists, but they were averse to saying anything. For this especial case, I suggested ovarian transplantation, which was declined. Later the uterus was removed and the woman recovered. I believe that when it is necessary to remove both ovaries, it is well to take out the uterus at the same time. Undoubtedly, there is an ovarian secretion, but I do not see how reflex irritation from the uterus could bring about such a mental condition as was present in this patient.

Dr. L. F. Schmauss, Alexandria, Ind.: One will more often be disappointed in doing conservative surgery than in doing radical surgery. It all depends on what we mean by so-called radical or conservative surgery. Some men are said to be radical when they remove everything that is diseased. That is not radical; it is simply a thorough and complete, a conservative operation, and these are the operations which give the best results, so far as the patients are concerned. It would be well if all cases would turn out as Dr. McRae has reported, but a surgeon must expect to be frequently disappointed. Many patients, if not completely relieved at the first operation, will not submit to a second, and will continue a life of chronic invalidism. Therefore, one can err as much on the side of "conservatism" as on the side of "radicalism." While examining ovaries and tubes before deciding what to do, the physician must be careful how he handles these organs, in order to avoid irritating them, causing the lighting up of old inflammation, cyst formation, etc.

Dr. John C. Murphy, St. Louis: This question of conservative surgery in the pelvis requires a broader and more varied experience on the part of the surgeon than does any other kind of surgery. If the surgeon is confronted with a condition which admits of no delay, it is important that he make up his mind quickly. In dealing with pelvic lesions, speaking from the standpoint of the gynecologist, I frequently see cases in which so-called conservative surgery has been done, and in which the work has been very incomplete, so that the patients have had to be subjected to unnecessary second operations. When the abdomen is once opened, no matter for what condition, the surgeon should have a sufficient knowledge of pathology to recognize what should be done. Unfortunately, however, some men have limited mentality, although possessed of some mechanical ingenuity. They take out ovaries and tubes, and frequently leave an infected uterus behind. And they think they are doing conservative surgery. I have had occasion to see numerous operations performed that were technically perfect, but the operator seemed to lack the training of the pathologist. I have seen surgeons operate on clinic patients whom they had not seen up to the time of their coming to the table. Someone else made the diagnosis, and asked the surgeon to operate for a certain condition. This certainly is to the detriment of the patient and not to the credit of the surgeon. Sometimes it is conservative to be radical. We must learn to differentiate between these conditions. There are thousands of women who are suffering from the results of incomplete surgery in the pelvis, which deters other sufferers from seeking the relief they might otherwise obtain. The surgeon should not so readily accept the sometimes incomplete diagnosis of his medical colleague, but should combine the science of the diagnostician with the art of the operator. The only conservatism worthy of consideration is that which puts the patient in the best possible condition to enjoy the pleasure of living.

Dr. Floyd W. McRae, Atlanta, Ga.: I agree with Dr. Baldy, that surgeons, as well as gynecologists, ought to be diagnosticians. I do not believe that there is any real antagonism between surgeons and gynecologists. There is not a good gynecologist who is not also a good surgeon, and any good surgeon is capable of doing most gynecologic operations. I do not believe that Dr. Baldy, or any other surgeon of experience, operates in these medical cases to which I referred. One of the principal points in my paper was that we must make a diagnosis. Dr. Murphy referred to one point of which I spoke, and that is operating on patients without making a previous examination. We should not go into these cases blindly, because that is when and where we make mistakes. Without doubt, many operations are done radically when conservative procedures would have been better. Often infections in the pelvis have practically jugulated themselves. We can do conservative surgery in these infective cases, and we can do much to preserve to the woman her womanliness. I have yet to see a young woman, who has had tubes, ovaries and uterus removed, and who is satisfied with her condition after five or six years. The younger the woman the more important it is for us to conserve these organs, or even to transplant at least a portion of an ovary into the uterus, saving enough of the ovary to prevent an artificial menopause. False deductions are made from improper diagnoses, improper appreciation of pathology, and lack of care in doing this work. I would rather operate twice or thrice on one patient and preserve her womanliness than do a complete operation and make of her one of those hapless individuals described in my paper.

A New Method for the Differentiation of Bacterial Species.—In a second report on the influence of bacterial endotoxins on phagocytosis (*Nature*, Nov. 24, 1910), L. S. Dudgeon, P. N. Panton and H. A. F. Wilson say they have failed to demonstrate in any of their experiments any action of the endotoxic substances on the leukocytes; experiments of allowing bacteria to be exposed to the action of specific endotoxic substances furnished similar results. They confirm those published in their first communication that the phagocytic result was dependent on the interaction of endotoxin of serum. They have found, in the case of normal serum, that the amount of phagocytosis permitted when bacteria and endotoxin interact is not related to the amount of hemolytic complement present. The action of the endotoxin seems to be specific even with such closely related organisms as the typhoid and paratyphoid types and they suggest that this method may be employed for the differentiation of bacterial species. The amount of endotoxin has been shown to be strongly hemostabile.

THE DIAGNOSIS AND TREATMENT OF CHRONIC INTESTINAL INDIGESTION IN CHILDREN *

SAMUEL M. HAMILL, M.D.
AND
KENNETH D. BLACKFAN, M.D.
PHILADELPHIA

This paper relates exclusively to chronic intestinal indigestion in children beyond the second year of life. It is not our intention to go into a detailed description of the condition, but rather to point out certain of its features which are of special interest and importance. Its etiology, as is well known, includes bad conditions of hygiene, food of poor quality, improperly prepared foods, overeating, eating at improper intervals, too rapid eating, insufficient mastication, defective teeth, exercise too soon after eating, fatigue, insufficient hours of rest, educational over-work, nervous influences, etc. Any and all of these conditions may result in disturbances of the gastro-intestinal tract in children who are primarily entirely normal and eventually bring about the form of disturbed digestion under consideration.

In addition to the causes mentioned it must be borne in mind that many children, either as a result of inheritance, previous acute illness or environment, suffer from constitutional debility which predisposes them to diseases of the gastro-intestinal tract.

While chronic disorders of the intestinal tract may be secondary to disturbances of the gastric digestion or the product of recurring attacks of acute gastro-intestinal disturbance, one must not lose sight of the fact that in a large percentage, if not the majority of cases, the condition is primary, and it is in this group of cases, which eventually result in the more pronounced types, that the earlier symptoms are frequently overlooked.

In the routine examination of the stools of apparently normal children, foul-smelling feces, which may or may not contain particles of undigested food, are a common finding. With these results as a guide a closer examination of the donor will often result in the establishment of other symptoms of disturbance of the intestinal digestion of which the child has never complained and which have passed entirely unrecognized.

Not infrequently, however, this condition of the stools is the only evidence one can discover, and it may continue indefinitely as the only symptom. It is well, therefore, to remember that chronic indigestion may and usually does persist for many weeks or months in a mild form, and at this stage its recognition is especially important, as therapeutic measures are much more promptly effective when applied early than in the later course of the disease.

The only satisfactory way of making the diagnosis of these milder forms, as has been indicated by the foregoing statements, is by an examination of the stools. Questioning the parents or child as to the regularity in movement of the bowels or condition of the stools is fruitless. In the first place, comparatively few parents give answers based on observation. They may insist on the child going to the toilet each day and the child may respond and have a movement, which is reported to the parent as satisfactory; but it is manifestly impossible that the child should know the color, odor and general appearance of a normal stool—as a matter of fact, there are few adults who do—consequently the statements of the parent or child cannot be accepted as indicating the actual conditions.

Quite recently one of us referred to a fellow-practitioner, a highly intelligent adult, who was suffering from insomnia and an associated group of symptoms which are commonly included under hypochondriasis or neurasthenia. The patient stated that he had been having a normal stool each day immediately after breakfast since childhood. The stool, which was sent to the laboratory for examination, was dark-green in color; macroscopically it contained undigested vegetable and meat fiber and the odor was indescribably bad. When the patient was told the character of the stool he remarked that he knew the odor was bad, but he supposed, since this had been the odor of his stools for many years, that it was normal. This serves as an illustration of the unreliability of the patients' statements as to the character of the stools.

It is manifest, therefore, that if satisfactory data are to be obtained the stools must be examined by the physician, and not on one occasion only, but several times at intervals of some days, since it is not uncommon for the child to occasionally have fairly normal stools, even in long-standing cases.

In order to appreciate one's findings it is necessary to have some idea of the appearance of normal feces. While the consistence and form may vary within certain limits, according to the character of the diet, we consider a stool to be normal when it is of faintly alkaline, amphoteric or neutral reaction, well-formed, light or medium brown in color, and has only a slight and not a noteworthy offensive fecal odor. It should show no evidences of fermentation and only slight traces of mucus should be present. Microscopically a normal stool shows, besides vegetable cells, poorly striated muscle fibers, leukocytes, bacteria, etc., no starch granules, and, if any, only a few neutral fat globules, soaps or crystals.

In intestinal indigestion the stools show evidences of abnormality depending on the particular element in the diet which is being less satisfactorily disposed of. Macroscopically the stool may be unformed or only partly formed, whitish, light brown, greenish or dark brown in color, and show an increase in offensiveness referable and in proportion to the increase of the putrefactive processes. It may be semi-solid, soft or mushy, or, on the other hand, hard and dry. It may contain undigested particles of muscle or vegetable tissue, show varying degrees of fermentation and varying amounts of mucus. Microscopically the stool may show large numbers of vegetable cells, fairly well-striated muscle fibers, starch granules, and, in the cases due to disturbances of the fat digestion, excessive quantities of neutral fat, soaps or crystals.

In the cases with marked abdominal symptoms the stools may show an exaggeration of the foregoing picture. The consistence may be very loose, or watery, and the fermentation marked enough to produce almost constant bubbling on the surface of the stool and the odor offensive in the extreme.

It is well to remember one point that has been referred to, namely, that the stools are often continuously offensive without containing particles of undigested food. This condition may not necessarily indicate a disturbance of the digestion of such character as we are considering, but may be the product of practically any

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

condition which will bring about a general lowering of nutrition, such as chronic infection through the lymphatic tissues of the nasopharynx or the faucial tonsils. In consequence there evidently occurs in the intestinal tract a diminution in resistance to the multiplication of the putrefactive bacteria without any material interference with its digestive function.

A careful study of the urine is of value in directing one's attention to disturbed intestinal digestion when the stools show no evidences of abnormality. The general characteristics of the urine as a rule show no changes, and, although it has been stated that there is an increase in albumin, this has only occasionally been true of the cases observed by us. We can conceive that certain changes might be produced in the functionating power of the kidneys, especially in the long-standing cases, which would result in an increased elimination of albumin. More commonly indican, phenol and urobilinogen are present in amounts depending on the degree of the intestinal putrefaction. These products may appear either alone or in combination, and, though usually associated with disturbances of the protein digestion, are sometimes present when the putrefactive process depends on other causes.

The manifestations aside from the stools may vary from practically no subjective symptoms to the most extreme clinical picture that one can depict. The symptoms are by no means restricted to the intestinal tract; in fact, the absence or mildness of the abdominal symptoms may be so striking as entirely to obscure the actual seat of the primary disturbance. The cardiovascular and nervous systems sometimes furnish the bulk of the symptoms; coldness and blueness of the extremities, fits of pallor, even amounting to syncope at times, palpitation and irregularity of the heart's action are common symptoms on the part of the circulation, and, together with the wasting, which in the long-standing cases is constant, there may be considerable anemia, which is usually, however, more apparent than real.

On the part of the nervous system there is no limit to the manifestations, and it is to these that we wish particularly to draw attention. The most common nervous phenomena are restless sleep, muttering during sleep, night terrors and sometimes insomnia. There is a general condition of restlessness and irritability and inability to concentration of effort, especially mental effort. These children are apt to do badly in their studies. They frequently drift into a clinical picture which in the adult would be defined as neurasthenia, and after this condition of nervous unbalance has been well developed convulsive seizures sometimes occur.

Not once but many times we have had these cases come under our observation, with the diagnosis of epilepsy and a hopeless prognosis as to recovery, and it is this fact more than any other which has stimulated us to present this paper, because we believe that the convulsive seizures occurring in this condition are frequently, if neglected, the beginning point of what later develops into so-called epilepsy. It has been our experience that in these neglected cases the history has shown a tendency to increasing frequency of the convulsive seizures; in other words, each convulsive seizure has rendered the nervous system more unstable and, therefore, more susceptible to insults from the toxic products which are constantly forming. The result is that the habit of fits becomes well established and eventually the resistance is so slight that the subject is to all intents and purposes an epileptic.

The relationship between chronic disturbances of the intestinal digestion and convulsive seizures cannot be too strongly emphasized. It is almost criminal to assume that, because any child has had a series of convulsive seizures lasting over a period of months or even a year, it is necessarily epileptic. Such an assumption is a most liberal contribution to the production of epilepsy.

The proper attitude to take toward a child with such a history is that there is a tangible cause for the attacks, which must be searched for through every possible avenue until it is determined and eradicated. The frequency with which it can be traced to these chronic conditions of the intestinal tract will be surprising and enlightening.

The fact that certain children suffering from chronic disturbances of the intestinal tract show more marked nervous phenomena than others is difficult to explain. The relationship of these symptoms to inherited weakness of the nervous system or to inherited tendencies which result in nervous instability is very commonly emphasized. We find certain writers describing under the headings of neurasthenia, nervousness, lithemia, chronic gastro-intestinal disturbances, chronic intestinal indigestion, constipation, etc., practically the same varied group of nervous symptoms. While neurasthenia is not accepted by some pediatrists as occurring in early life, it is by others, and, as to etiology, it is usually defined as hereditary and acquired. We are probably all willing to admit that we are not born into the world endowed with the same amount of nervous resistance. Unquestionably each individual differs from others in this respect, and some have very little nervous resistance. These latter are the ones defined as the hereditary neurasthenics. Their nervous force is so limited that the slightest variation from the normal routine of life results in the production of nervous symptoms; indeed, it is said that these may occur without an exciting cause. These cases are described by some pediatrists as of easy recognition even in early infancy through the occurrence of such reflex phenomena as abnormal tendency to fright (as starting on the occurrence of any sudden noise), abnormally light sleep, continuous crying day and night, etc.

Acquired neurasthenia is usually attributed to overstrain, either mental or physical, and to certain emotions. These latter causes are rarely active in children and, therefore, one must assume that in early life the large majority of instances of neurasthenia are manifestations of a hereditary weakness unless certain other factors, not active in adult life, are capable of producing neurasthenia in children.

It seems to us that this group of nervous symptoms which is common to so many disorders in early life should be classified either as neurasthenia caused by the conditions with which they are associated or that the term "neurasthenia" should be restricted to an exceedingly small group of cases or eliminated entirely from the category of diseases of child life. We incline to this latter view because we believe that the instances in which these nervous manifestations exist, apart from all exciting causes, are practically unknown. They may be dependent on any one of a number, such as bad environment, adenoids and enlarged tonsils, defects in vision, and the chronic disturbances of the gastro-intestinal tract. Unquestionably this latter group is more largely responsible for the nervous phenomena of children than any of the others, and this is especially true of chronic intestinal indigestion. In certain children the nervous system may be especially susceptible because of hereditary deficiency; in others the prolonged action of toxic products on the nerve centers results in an acquired susceptibility with the production of the same phenomena.

In either event the fact remains that in chronic intestinal indigestion there is a large group of nervous symptoms which are dependent on the toxic substances, which are absorbed or retained in consequence of the abnormal conditions of the intestinal tract—a fact which we daily demonstrate by bringing them under complete control by correcting the intestinal condition.

The important point to bear in mind is this causative relationship, since there is grave danger of accepting the nervous symptoms as the disease without endeavoring to determine the primary condition and relieving it. Probably all of us have been inclined to look on this condition of nervousness associated with chronic intestinal indigestion in early life as the internist has looked on neurasthenia in the adult, viz., as often more or less hopeless from the therapeutic standpoint. This attitude has made the handling of these cases difficult.

We have shown a tendency to neglect them. The bad results of such neglect are far-reaching. The longer the condition lasts the more numerous and fixed the symptoms become. These children often pass out of childhood into early youth and on up to adult life, becoming more fixed in their ill health and correspondingly more neglected as the treatment of their condition becomes more difficult. They swell the number of so-called cranks, hypochondriacs, neurasthenics and hysterics among adults, a large percentage of whom could have been given comfortable, useful lives if the true nature of their condition had been recognized in childhood.

Aside from the symptoms referred to these cases of chronic intestinal indigestion sometimes manifest another group of symptoms which may be misleading from the standpoint of diagnosis.

Distention of the abdomen does not develop in all instances, but in the cases in which the nutrition of the muscles suffers the abdomen may be greatly distended. The thinning out of the abdominal muscles lessens the support to the abdominal contents; this lack of support, together with the weakening of the intestinal wall and the putrefactive processes within the intestine, brings about a ballooning of the abdomen which may become extreme; when vomiting of toxic origin, which may persist for some days, is added to these symptoms the clinical picture of tuberculous peritonitis is strongly suggested and sometimes eliminated with considerable difficulty, especially the fibrous form. The only satisfactory evidence on which peritonitis can be excluded is the history of the case, continuous observation over a period of weeks, the absence of the characteristic doughy or infiltrated feeling of tuberculous peritonitis, and the absence of masses within the abdomen, signs which may, however, be entirely lacking.

There is one other symptom to which we wish to call attention, and that is a peculiar form of dyspnea which we have somewhere seen aptly described as "sighing respiration." This symptom is most marked after meals and especially after the evening meal or when food is taken immediately after severe exercise. It is associated with a feeling of epigastric distress or pressure and consists of inability to get a sensation of satisfaction from respiratory effort. It is usually associated with increased distention of the abdomen, especially the distention of rather sudden origin. The child will take a full deep inspiration, which is followed by a sighing expiration. It sometimes becomes almost continuous for a period of days and in older children we have seen it produce considerable alarm. Exercise will sometimes increase it, but generally it lessens abruptly or entirely disappears when the attention is distracted by occupation. On what this symptom depends we are uncertain. Whilst usually associated with increase in the abdominal distention, the latter rarely seems sufficient to mechanically interfere with the proper function of the intrathoracic organs. It would seem to be more properly attributable to some toxic effect on the centers of respiration and probably always exaggerated by psychic influences.

Edsall has suggested that since in gastro-intestinal conditions marked acidosis is not uncommon it is entirely possible that a "subacidosis" may overstimulate the respiratory centers sufficiently to produce this symptom.

Haldane and Priestly have shown that carbon dioxid is the normal stimulant to the respiratory center. It has also been shown that other acids may have the same effect. Therefore it is not a lack of oxygen but the presence of carbon dioxid and other acids that produces respiratory effort.

Beddard, Pembrey and Spriggs have shown that in the coma of diabetics carbon dioxid tension may not be increased and that the blood can still absorb carbon dioxid freely, but that slightly excessive amounts of carbon dioxid in the respired air cause great excess of dyspnea.

Since this dyspnea is very often controlled by alkalies, and since acid intoxication is known to exist in diabetic coma, the authors referred to conclude that the organic acids produce the Kussmaul breathing by acting as respiratory stimulants.

In the light of these conclusions, and because of the striking similarity between the sighing respiration of intestinal indigestion and the Kussmaul breathing, the suggestion of Edsall would seem to provide the correct explanation.

TREATMENT

Coming now to the treatment of chronic intestinal indigestion, we would say that it divides itself into the following heads:

1. Absolute control of the patient—which means the full cooperation of the mother and nurse.
2. Hygienic treatment.
3. Dietetic treatment.
4. Medicinal treatment.

Unless one has the full assistance of the caretakers in carrying out measures of treatment, failure is a foregone conclusion. The first step in the treatment, therefore, consists in securing such cooperation. This can usually be done by a full explanation of the nature of the disease, its chronicity, the dire results which will inevitably follow neglect of the condition, by placing of a large share of the responsibility of treatment on the mother or nurse, where it rightly belongs, by the promise of cure if they cooperate, and by making them understand in the beginning that the treatment must be continued not over days or weeks, but months, and that drugs will be but a small factor in accomplishing results.

If the confidence of the attendants is thus obtained, the most important feature in the treatment is accomplished. In the children of the poor and ignorant, seen in the hospital clinics, one can obtain better results—in fact, one might say that the only way in which one can get thoroughly satisfactory results is—by placing them in the wards of the hospital for several weeks, as the conditions necessary for treatment cannot be secured in their homes.

Patients of this class unfortunately will only too often relapse after they have returned to their home environment. Much can be accomplished with such patients, however, by following them up in their homes through the medium of social workers or visiting nurses.

Hygienic measures are very important. Life in the open air, for its stimulating effect on the circulation and general toning effect, must be insisted on, and the sleeping-rooms must be cool and ventilated through wide-open windows. Properly regulated exercise is important, but this should be largely in the open air and always short of fatigue. Children must be required to eat slowly and masticate their food thoroughly, the common habit of bolting food to get away to school or to games being one of the causes of this condition. A period of rest should intervene between the taking of food and indulgence in active exercise. Very little, if any, physical exercise should be permitted after the evening meal. Long hours of sleep obtained by early retiring are essential.

The skin of these children is usually dry and inactive. It must be stimulated to do its work as an organ of elimination by the use of daily baths, rubbing, and inunctions, preferably with olive oil.

The kidneys must be kept active by the free use of water, which will also contribute to the lessening of constipation when it exists. Regularity in the evacuation of the bowels is necessary, especially in the presence of constipation. The child must be guarded against too close consideration of its symptoms, a result which is often brought about by undue anxiety on the part of the parents. Its environments must be cheerful and free of gloom. It must be relieved from all occupations which are depressing, especially from overwork in school.

Defective conditions in the teeth must be corrected and disturbing adenoids or tonsils removed, but only after the treatment has been continued long enough to bring about some improvement in the general health, and then by quick operations.

The nature of the diet depends to a large extent on the character of the indigestion. This can only be determined, as has been previously pointed out, by a careful study of the stools. If any one element of the diet has been badly handled, it must be withdrawn from the dietary, temporarily at least. Generally speaking such patients will do better in the beginning on a very much restricted diet, restricted even beyond the caloric needs in the individual case. One of the commonest errors in the treatment is the tendency to overcome the poor nutrition by full feeding. Obviously such a course is comparable only to adding fuel to the flames. These children are already the victims of too much food, and what their digestions need is not increased work, but rest. This can usually be most satisfactorily accomplished by the administration of a milk diet in some form. Where fats are badly handled, it is sometimes necessary to use diluted or even fat-free milks, and in some cases properly prepared buttermilk is useful. The milk diet should be continued until the stools give evidence of satisfactory digestion, after which the diet may be gradually extended, studying the stools the while and bearing in mind the elements in the food which have been poorly disposed of.

Usually the diet can be gradually advanced until a general well-rounded diet equal to the needs of the individual child has been reached. The heaviest meal should be given in the middle of the day, and the evening meal should be very light, as these children rarely sleep quietly on a full stomach.

It seems almost needless to say that all foods of recognized indigestibility should be permanently excluded and that the pernicious habit of eating between meals should be forbidden. Tea and coffee and other unnecessary and disturbing substances must follow the same course.

The use of drugs in this condition represents the least important part of the treatment. There is no specific, and, therefore, whatever drugs are given must be directed to the relief of certain symptoms.

We have used the so-called intestinal antiseptics for the control of putrefactive processes, but with entirely negative results. In the beginning of treatment and occasionally thereafter, a course of calomel followed by colonic irrigation will do much to relieve this feature of the disease. The intestinal washings seem especially effective in the cases with loose, watery, foul-smelling stools.

For the frequently associated constipation, one need rarely resort to the use of drugs. The free use of water on rising, evacuation of the bowels immediately after the morning meal, together with properly applied abdominal massage, and later the free use of green vegetables and laxative fruits, will invariably control this symptom.

As a temporary measure, we prefer olive oil enemas and non-irritant suppositories to laxative drugs. In the emaciated patients with marked abdominal distention, temporary mechanical support to the abdominal wall, together with muscle exercises directed to improvement in the tone of the abdominal muscles will contribute to the relief of constipation.

The bitter tonics, which are given more for their toning effect on the gastric mucosa than for their general effect, are the only tonics which are indicated. In short, if the conditions which are active in the causation of the disease can be controlled in the manner indicated under the preceding headings, the clinical picture will usually clear up without the necessity of drugs.

1822 Spruce Street.

ABSTRACT OF DISCUSSION

Dr. H. L. Coit, Newark, N. J.: I have seen a number of cases that correspond to this clinical picture, and it is well to remember that many cases of so-called epilepsy are amenable to treatment. Most of the cases I have seen have been referred to me by physicians who thought they had epilepsy to deal with. Physicians are too ready to use medicine in treatment of intestinal indigestion in children. without proper attention to the diet. I think we should study these cases carefully and question the mother closely, in order to determine the dietetic errors. In the treatment, an important part is the correction of the diet. It may be that milk is used with red meats, or milk is used at breakfast with fruit and sugar. In addition we find over-feeding the rule, with the consequent putrefactive intestinal decomposition. In these cases there are restlessness, sleeplessness, indicanuria, fits of uncontrollable anger and foul-smelling stools. We cannot remove the results of putrefaction with carbohydrate diet alone, nor with calomel, or castor oil, but I think that we can do it by the use of bichlorid of mercury. Corrosive sublimate was abandoned by the surgeon because it became an albuminate which was insoluble, and the same is true when given by the mouth, but when it is given with hydrochloric acid it probably reaches the intestine, although it may there be changed into some other salt which finally alters the malodorous character of the intestinal contents. It should be given with the tincture of the chlorid of iron and with considerable glycerin an hour before the ingestion of food in small quantities.

Dr. Charles Gilmore Kerley, New York: I agree with everything Dr. Hamill has said, but I want to emphasize one point that I think he did not emphasize sufficiently, and that is, the matter of rest in the type of child he discusses. All of the lower animals lie down and sleep or take a rest after a full meal if they have an opportunity, and then digestive function is carried on better. When an animal has to work after a full meal, the digestion and assimilation are not so good. This has been demonstrated time and again. We all know how much exercise is taken by children, especially children of school age. The amount of energy expended in their work is tremendous, and the energy that is expended *in play cannot be utilized in the* digestion of food. When we have wasted energy in a child we have invariably indigestion, malassimilation, malnutrition and neurasthenia. Keep these children in bed in the morning, and let them have their breakfast in bed and give them a modified rest cure. Then let them run about and play like normal children until luncheon in the middle of the day. Then have them rest again for an hour and a half and then allow them to run about until 6 p. m., when their evening meal is taken and then to bed. In that way the child gets all of the rest required and he conserves his vitality for the processes of assimilation and growth. If we let these children lead a child's life and see that they get sufficient rest, they will not get into the condition described by Dr. Hamill. One of our greatest errors in the management of young children is in permitting the extraordinary amount of work they do from morning until evening. If you don't believe that, take one of your own children and weigh him, and then give him this rest and weigh him at the end of a month, and you will find that the child will gain a pound or more.

Dr. L. T. Royster, Norfolk, Va.: Has Dr. Hamill made any observation at all in the matter of temperature during the convulsive seizures in the class of cases he mentions? Does he consider the temperature, either positive or negative, in any way suggestive of the diagnosis between that condition and epilepsy? I have asked a number of neurologists in this country that question and none of them seems to have thought of it to the extent of making an observation.

Dr. H. M. McClanahan, Omaha: The valuable thought in this paper to me was the possibility of *intestinal indigestion* and consequent toxemia leading to epilepsy. I have in mind a little girl who had repeated convulsions as often as once a week. She had chronic intestinal indigestion of the mucous type. After following out the course of treatment suggested by Dr. Hamill that child has absolutely recovered and more than six months have elapsed since a convulsion occurred. I am thoroughly convinced that, though the trouble was not true epilepsy, it was leading to epilepsy, and I am convinced that the convulsions were due to some toxins in the blood from the intestinal putrefaction. I believe more than most of you in the value of drugs, and I hope that I shall never become a therapeutic nihilist any more than I am a social nihilist, but I think that when the mother is given a drug to administer in these cases she is far more apt to carry out your treatment than if you depend absolutely on hygienic treatment. In the presence of constipation, especially the mucous type, the use of phosphate of soda is of value although its value is not great compared with that of rest and a correction of the diet.

Dr. E. E. Graham, Philadelphia: In considering the nervous symptoms Dr. Hamill speaks of, we should not lose sight of the fact that a convulsive seizure in a child is brought about by an entirely different cause from a convulsive seizure in an adult. In children the convulsion is commonly of reflex origin, while in the adult it is commonly the result of some organic disease of the nervous system. This only adds force to the statement that chronic gastro-intestinal disease may originate and produce epilepsy in the adult. The probability of convulsions due to brain injury in an adult is very remote, while it is very common in children. For many years I have made a study of the cases in which convulsions developed in infancy, and that study has proved to my mind conclusively that the young child who has a convulsion is very commonly the one who later develops epilepsy, and that probably the *convulsion*, due to gastro-intestinal intoxication, is the origin of the late epilepsy. In other words, a certain amount of damage to a child's nervous system predisposes it to epilepsy. Any condition that is chronic for months or years and predisposes the child to convulsions certainly establishes a future condition that will predispose that individual to epilepsy. This paper is valuable because it deals with a *condition* with which we are all brought into contact, though it is a type of trouble that the large majority of us are apt to overlook.

Dr. John Lovett Morse, Boston: I merely wish to emphasize the importance of regulation of the diet in the treatment of these cases. The only way in which the diet can be accurately regulated is by having the mother keep an exact account of what the child eats both as to quantity and quality and by repeated examination of the stools. In this way only can we determine exactly what the cause of the condition is. The only feasible way of disinfecting the intestine is by changing the bacterial flora, and this can be done only by changing the food. I want especially to emphasize the value of the carbohydrates in changing the flora in these conditions. Changing the intestinal contents by the carbohydrates changes the flora, inhibits the growth of the organisms which thrive on proteids, and hence prevents the formation and absorption of the products of the decomposition of proteids. When Dr. Coit spoke of protecting the bichlorid by hydrochloric acid, I wondered how many inches down the intestinal tract it would go before it was neutralized.

Dr. Fritz B. Talbot, Boston: There is a general impression that it is a very difficult procedure to make an examination *of the stools. From three to five minutes are required to* make the examination and it gives important information concerning the digestion of fat, starches and meat. I have been impressed by the fact that an excess of meat and starches is relatively uncommon and that an excess of fat is common in these cases of intestinal indigestion. The reason for this is that fat is the component of the food, which the parents are more likely to give in excess to a child who is run down.

Dr. Samuel M. Hamill, Philadelphia: Dr. Kerley is probably right in believing that I did not sufficiently emphasize the importance of rest in the treatment of chronic intestinal indigestion. He believes in prolonging the night's rest by giving these children their breakfast in bed. I am inclined to believe that in these cases many hours of consecutive rest result in the accumulation of toxic products which are very depressing in their effect. It is my custom, therefore, to have these children get up at a comparatively *early hour, and, in order* to secure a satisfactory total rest for the twenty-four hours, to have them rest at later periods of the day. I think that rest is so important that I sometimes have these children separated from other children by sending them to the country in charge of a nurse, where they *can* be under better control and where a quiet restful life is possible. I have not studied the temperature curve in the cases having convulsions, but I do not believe it would prove of value in the differential diagnosis from epilepsy.

As to Dr. Graham's remarks, I am perfectly willing to *admit that* children are more susceptible to reflex influences than are adults, but I do not believe the convulsive seizures in these cases are of a purely reflex nature. They are of toxic origin, as are the other symptoms.

I do not want Dr. McClanahan to believe that I am a *therapeutic nihilist.* I give drugs to these patients but it is exceedingly important to emphasize the fact that drugs are overemployed and that they are frequently given without the slightest indication. I realize that it is desirable to console the mother by giving some medicine to the child, and I think we *can do this* honestly by prescribing some valuable drug, but we must make her realize the limitations of drugs, for unless we emphasize the necessity for general *hygienic* treatment the mother will neglect this and pin her faith to *the drugs.*

Dr. Morse spoke of the value of getting a record from the mother of the exact dietary of the child. I never treat a child without doing this, and I think it is exceedingly important. I secure not only a list of the various foods administered, but also a statement of the amounts of each food. The examination of the stools, as has been suggested by Dr. Talbot, is not a difficult procedure, and one can gather much valuable information from the macroscopic study alone. The microscopic examination is important, but not so much so as the macroscopic. The sooner we realize that the examination of the stools is an easy procedure, the sooner we shall employ it as a routine measure.

NITROUS OXID AND OXYGEN ANESTHESIA *

WILLIAM D. HAGGARD, M.D.
NASHVILLE, TENN.

The advances in the use and perfection of nitrous oxid anesthesia since the report of the Anesthesia Commission on this subject, at the meeting of 1908, seem to consist of the following:

1. The employment of this agent, with modifications, as the routine anesthetic in several of the large clinics of this country.
2. The demonstration clinically and experimentally of the advantages of nitrogen oxid and oxygen over ether, in the prevention of shock, the conservation of immunity and its value in the case of the handicapped patient (Crile).
3. The establishment of rebreathing of nitrous oxid and oxygen for two or three minute periods, as harmless and beneficial, with the great reduction in cost of this anesthetic (Gatch).

It has already been shown that nitrous oxid is the safest of all anesthetics and the most pleasant to take; that it requires the shortest time for induction; that there is almost immediate recovery after its discontinuance, and that it has no bad after-effects. There is no stage of excitement, and excitement is absent when the patient returns to consciousness. Dentists, who have used it in short administrations for many years, state that literally millions of administrations have yielded an infinitesimal number of deaths.

It is not absolutely free from danger, however. Death can occur from its continuous administration, without admission of air or oxygen in from two to four minutes. In overdosage, death is caused by asphyxiation and cardiac inhibition. In the fatal animal experiments, sudden arrest of the heart in overdistention was observed. The danger-signals with this anesthetic are:

1. Deep and persistent cyanosis.
2. Depression and slowing of the pulse.
3. Vomiting.

Cyanosis is the first indication of trouble, and gives startling warning of impending danger. Discontinuance of gas and giving of oxygen, which should be always at hand, uniformly and promptly dissipate all danger.

Crile has shown in the physiologic laboratory that animals under nitrous oxid withstand shock-producing trauma much better than under ether. The resistance of animals rendered pathologic from infections, hemorrhage, and hyperthyroidism, likewise, was strikingly better under nitrous oxid than under ether. These laboratory observations were corroborated by the histologic examination of the primitive ganglion cells of the central nervous system. Crile's recent investigations in cytolysis show that there is decidedly more destruction of chromatin after ether than after nitrous oxid. Again, there is no lowering of the phagocytic power after nitrous oxid, as after ether. Nitrous oxid does not reduce hemoglobin or cause any permanent blood change. There is no acetone or indicanuria as a result. Postanesthetic complications are absent.

Although oxygen was used by Andrews with nitrous oxid as early as 1868, some of the later apparatus provided for the admixture of air. Bevan employs this gas and air mixture with success, and I have used it in a series of over 100 cases. This mixture, however, does not provide such smooth anesthesia as does the mixture with oxygen. On account of the large atmospheric content of nitrogen, if enough air is used to do away with cyanosis entirely, it so dilutes the mixture that complete anesthesia is interfered with. While cyanosis is not desirable and can be prevented by the addition of oxygen, yet it should be understood that the cyanosis is not nearly so dangerous as that cyanosis produced by ether or chloroform—a cyanosis due to cardiac and respiratory depression.

It seems to have been established by Gatch that rebreathing nitrous oxid and oxygen in periods of two minutes is not only perfectly safe, but helpful to respiration, circulation and blood-pressure. Moreover, rebreathing reduces the expense greatly, which was partly responsible for the somewhat restricted use of this agent. Rebreathing seems to be more satisfactory than the continuous administration of the gas. The respirations are deeper and fuller, and the pulse is slowed by the therapeutic excess of carbon dioxid stimulating the center of cardio-inhibition. The temperature is slightly raised. The argument for rebreathing is that carbon dioxid under 4 per cent. concentration is non-toxic; that in normal and somewhat increased amounts in the blood it is the normal stimulus to the venous wall; that the abolition of venous tonus and not arterial is the primary cause of failure of circulation in shock. Carbon dioxid stimulates the cardio-inhibitory, vasomotor and respiratory centers, and an increase such as is afforded by rebreathing during gas and oxygen raises the blood-pressure and is thus an easily available preventive of shock. The loss of body heat by expired air is conserved by rebreathing and artificial warming of the gases is rendered unnecesary.

The apparatus of Gatch providing for rebreathing is extremely simple, portable and inexpensive. It has a rubber sleeve that fits snugly and conveniently over the face-piece, preventing leakage of gases and the ingress of air which checks the anesthesia. The patient can be given air or gas, with or without oxygen, and made to breathe the mixed gases to and from the bag. Even a little air allowed to mix the gases spoils the anesthesia. The apparatus has an attachment permitting ether to be added when needed for short periods, all without removal of the mask, until the anesthesia is to be permanently withdrawn. It is a very powerful etherizing device when needed.

It is not necessary to attempt to give any arbitrary percentage of oxygen. Just enough to dispel the cyanosis is the aim and, roughly speaking, a puff of oxygen in each bag of nitrous oxid that is to be rebreathed is sufficient. Keep the patient pink, is the rule. If the color cannot be kept good, it is better to give ether by the open method.

---

* Approved by the Committee on Anesthesia of the American Medical Association.

Not all patients, notably not the very robust and alcoholics, can be sufficiently relaxed without disagreeable cyanosis. In these, ether given for three or four minutes in the mask or by the open method, will usually accomplish relaxation and oblivion. The quantity of ether is negligible. When rigidity is overcome the gas may be resumed. A little ether, so small in quantity that the patient is never aware of it, is given in about three-fourths of the abdominal cases at Johns Hopkins Hospital (Gatch). The post-operative discomfort is less with a little ether and no cyanosis than with no ether and prolonged cyanosis. Pronounced cyanosis is apt to be followed by headache.

Teter estimates that a small quantity of ether given in this way will be necessary in about 10 per cent. of the cases. In laparotomies three, five or seven minutes of ether will be required in about 40 per cent. of cases.

Gas and oxygen can be used with impunity where ether is contraindicated, i. e., in kidney disease. Nitrous oxid has also been employed in advanced pulmonary lesions and seems to have caused no mortality. It is particularly helpful in those desperate cases from any cause that urgently demand operation and yet are so risky that the surgeon realizes that ether or chloroform is the added weight which depresses the beam.

The borderline cases in which the operator seriously questions the wisdom of trying to do anything, may have surgical aid extended safely, so far as the anesthetic is concerned, by nitrous oxid and oxygen, but only at the greatest hazard with ether or chloroform. Moreover, the inevitable, though small, anesthetic mortality from pneumonia, anuria, fatty degeneration of the liver, etc., can be be prevented.

The chief class of cases rendering nitrous oxid unsafe is that of heart lesions, whether myocardial or valvular.

Anesthetization with nitrous oxid is incontestably more difficult than ether. It requires special training and expertness to acquire the technic. Crile has had it administered practically as his routine anesthetic in over 1,000 cases. There has been one death six hours afterward which he charges to the anesthetic. With the increased experience acquired by his special anesthetist he feels that this fatality could now be averted.

The danger, therefore, is not so much in the agent as in the administrator, but this is equally true of the other anesthetics. The simple cases should be chosen first.

It is therefore not adaptable for the all-round use of the general practitioner, but will grow greatly in popularity in the highly perfected clinics, in hospitals with expert permanent anesthetists, and with those who specialize in anesthetics. Fortunately most of the major surgery and graver traumas are cared for under these conditions, and thus the desperate chance patient may have this added safeguard and adjuvant to life saving.

Gas and oxygen are not only indicated where the risk is great, but routinely they are a special boon to patients who have been operated on before and who have a more or less justifiable and vigorously expressed dread of the primary "smothering" effects of ether, and the secondary feeling of *mal de mer*.

Nitrous oxid can be safely administered for two or three hours, and at Johns Hopkins Hospital where it has been used routinely on the surgical side in over 1,000 cases, Gatch kept one patient under its influence for five hours without ill effects. It can be given longer with safety than any other anesthetic.

A preliminary dose of morphin gr. 1/4 and atropin gr. 1/150 or half that amount is useful in the majority of cases to assuage the fear of the anesthetic and of the operative ordeal. Anesthesia is induced more easily and proceeds more tranquilly, a smaller quantity is required and the after pain is annulled. No food or drink should be given for at least four hours prior to operation. Do not begin the operation too soon.

Crile gives 1/150 gr. scopolamin or less two hours before operation. It induces the "twilight slumber" and obliterates any fright or even anxiety about the operation. The effect, and with the preliminary dose of morphin followed by the anesthetic lulls the patient into a drowsy somnolence which deprives the entire day of painful recollection.

Nitrous oxid and oxygen anesthesia with the apparatus not permitting rebreathing, costs about $5.00 an hour. With the apparatus of Gatch, obtaining the other benefits of rebreathing, the cost is reduced to $1.00 or $1.50 an hour. This cost may be further greatly reduced by installing, for a few hundred dollars, a permanent plant in the basement of the hospital, for the manufacture of nitrous oxid. It can be piped to the operating-room, thus doing away with the noise made by the escape of the gas under pressure in the cylinders.

Continuous auscultation of the heart by a phonendoscope, as practiced by Cushing and advised by Teter, gives accurate information, and allows both hands of the anesthetist to be employed with the patient and the apparatus.

ANESTHESIA IN TRAUMATIC SURGERY*

GASTON TORRANCE, M.D.

BIRMINGHAM, ALA.

On being asked by the committee to report on anesthesia in traumatic surgery from the Birmingham district, I sent a circular letter to a number of surgeons in this country and abroad, asking them to give their experience and observations in regard to this subject; and below will be found a condensed form of the reports submitted by them.

Professor Eiselsberg writes that in the Vienna clinic they have a special station devoted to traumatic surgical cases. He advises that as small an amount of the anesthetic be used as possible. No morphin or scopolamin should be used in fractures of the skull as there is danger of sudden collapse. Morphin should precede the anesthetic in fractured ribs, thereby avoiding dyspnea. He prefers using Billroth's mixture (chloroform, ether and alcohol) followed by ether where a general anesthetic is to be used. Spinal anesthesia is to be used only where others are contra-indicated. He has never observed a death from the anesthetic. The greatest precautions are to be taken where a general anesthetic is used as traumatized patients are much more sensitive to the effects of anesthetics than other. Where possible the operation should be postponed until the first period of shock has been passed.

Dr. Charles H. Mayo says that he and his colleagues have practically no traumatic cases in their surgery and that they have had very little opportunity to observe the effects of anesthesia in this class of work.

Dr. George W. Crile writes as follows:

> Wherever possible, nitrous oxid oxygen anesthesia is used. I base my preference on the observation that under nitrous oxid anesthesia there is less shock than under ether. That is,

---

* Approved by the Committee on Anesthesia of the American Medical Association.

> either nitrous oxid offers a certain protection or ether does a certain amount of harm, I am not prepared to say which it is. In cases of intracranial pressure I should use only local anesthesia In these cases, when anemia of the brain is threatened, a little pressure is often sufficient to cause a fatal degree of anemia Likewise, if in fractures the shock is not deep, I should prefer ether, because there is better muscular relaxation and better adjustment could be made Whenever practical during operations, I cocainize the large nerve trunks. There is no doubt that spinal anesthesia is accompanied by less shock, but I have not as yet adopted it as a general operative anesthesia

Dr. John C Munro, since resigning from the Boston City Hospital six years ago, has seen very little traumatic surgery; prior to that time his experience was very large His observations have been that any general anesthetic, except in short operations, increased the shock of the trauma. Ether acts as a temporary stimulant but, beyond ten or fifteen minutes, is a cause of increased shock. He does not like cocain locally on account of the increase of time required for operation and the increase in psychic depression. Ether is superior to chloroform in chest injuries. A general anesthetic should be used to prevent shock from pain that comes with handling fractures, etc, and it should be used if it will shorten the operative procedures and prevent prolonged exposure of the patient

Mr Rutherford Morison, Newcastle-on-Tyne, holds that the danger of the anesthetic depends more on the skill and care of the anesthetist than any other factor and that other considerations are insignificant He asserts that shock is combated by the anesthetic and especially the open ether method plus oxygen. In any and every case the anesthetic should be preceded by morphin and atropin. With a skilled anesthetist his preference is for chloroform by Vann Harcourt's inhaler for everything, with an unskilled anesthetist ether offers a larger safety margin

Dr. T. C. Witherspoon, of Butte, Mont, treats a large number of traumatic cases from the mines and railroads; he relies entirely on ether as a general anesthetic and eucain and cocain for local use A local anesthetic is always used where it will suffice He has not used spinal anesthesia in this class of cases but thinks it would be more useful and safer than ether. He has never seen a death attributable to the anesthetic either in traumatic or non-traumatic cases

Mr Robert Jones, of Liverpool, says that he has been much interested in this subject. He writes

> About fourteen or fifteen years ago, when I was appointed operating surgeon to the Manchester Ship Canal Works, where we had three hospitals and 20,000 people working, I had a great deal to do with the administration of anesthetics during the condition of grave trauma, and in such cases as double amputation of the leg, or amputation of thigh and arm, where disinfection and operation had to be rapidly done, I found the results very unfortunate, so many apparently never recovering from the anesthesia combined with the shock.
>
> I made a good many experiments as to anesthesia administration, and found shock (as evidenced by pulse and temperature) more pronounced after chloroform than after ether, but that the administration of either resulted in a certain degree of shock I also noted that the navvy, who is a very obstinate man in this country, would come in, perhaps with badly crushed legs which required amputation, but which he refused to have amputated To my astonishment, these patients often lived on until sepsis or some other trouble supervened, and some lived on until, weeks or months afterward, operations were allowed One also noticed that even after very trivial operations, patients were sick and generally upset, and I became convinced that, in conditions of grave shock, if one could operate without an anesthetic, the greatest possible advantage would accrue I therefore determined that, in all my big smashes, I would behave as the surgeons used to behave in the days of old and amputate without any anesthetic at all I used to give them plenty of hot water to drink, and, after preliminaries, I amputated as rapidly as I could. The patient hardly ever complained of pain except when the knife went through the skin, and nearly always when the bone was sawn there was a fall in the pulse and a sigh or groan From the time I adopted this line of treatment, my results show astonishing improvement, the mortality became markedly lessened, the patient (instead of sleeping on to eternity) conversed with one immediately the operation was over, and in some instances the pulse gave the impression of having improved By this method I have amputated both legs and an arm in the same patient, and altogether operated in twenty seven cases of grave lesions Unfortunately, the hospital was burned down and my precise records were destroyed, so that I have never been able to publish the results in detail, but have depended on impressions Although I had almost a rebellion on the part of the staff when I started this method of treatment, they all became enthusiastic when the results were appreciated
>
> I will give another case in point bearing on the same question My house surgeon from the Southern Hospital telephoned to me one evening, about fifteen years ago, that a man had been badly smashed by being taken round a wheel in a forge The shoulder was evulsed, the pectoral muscle lay outside his chest, the patient was pulseless and the house surgeon said that it was no good coming to see him I went up however, and found the man pallid, with ribs broken and the pulse barely appreciable in the other arm With a pair of scissors I clipped the muscle slowly through, tying every little vessel and taking half an hour or more in trimming up and removing the whole of the upper arm and the house surgeon at the end told me that his pulse was now quite clearly to be felt

Dr John A Wyeth of New York, considers chloroform more dangerous in any and all forms of surgery than ether, ether more dangerous than nitrous oxid, and nitrous oxid combined with oxygen the least dangerous of all general anesthetics He advises a close study of each case before deciding on an anesthetic, and thinks that a local anesthetic can often be used instead of a general anesthetic

Dr J. J Buchanan of Pittsburg finds that in cases of pronounced shock, in which a general anesthetic is contra-indicated, operations of necessity, such as amputations, can be done without anesthesia of any kind, without materially adding to shock, if performed with celerity. He finds, also that, under similar conditions, abdominal section and internal manipulations are well endured without anesthesia, if manipulation is not too complicated or prolonged A general anesthetic is contra-indicated in head injuries with pronounced cerebral symptoms, also in collapse of the lung from external open injury

Dr John B Roberts of Philadelphia thinks that ether acts as a heart stimulant and lessens shock, but that it may be only temporary. He thinks death is usually due to a "bad etherizer" He has had little experience with other anesthetics

Dr. Joseph C Bloodgood of Baltimore, says

> In my experience all anesthetics, except perhaps nitrous oxid, as they are toxic substances, would rather increase the effects of trauma It is quite true that indirectly they may do good when they allow us to remove all cause of the shock greater than the anesthetic itself, for example, hemorrhage, infection, perforation in peritonitis, pancreatitis, lacerated and crushed limbs Here we must risk the danger of the anesthetic in order to remove a condition which is keeping up the shock I am also of the opinion that there is a definite relation between the degree of seriousness of the

> condition and the shock and the part of the body subjected to operation or injury. It is my opinion that the anesthetic acts about the same except in surgery of the chest. The anesthetic of choice to-day with me is nitrous oxid gas and oxygen; next, nitrous oxid combined with ether; next, ether alone by the drop method; chloroform I rarely employ; spinal anesthesia never.

Dr. A. J. Ochsner of Chicago says that he simply uses ether in all cases whether traumatic or non-traumatic. He has kept records in a large number of cases in which chloroform was given until anesthesia was accomplished, then ether, except where contra-indicated. Then for a time he used nitrous oxid gas but has gone back to the use of ether by the *open drop method.*

Professor Rovsing of Copenhagen, says:

> I use always, in traumatic as in ether cases, only the morphin-ether narcosis with the Wanssleer apparatus. I have never seen an accident, never had but one disagreeable moment in using this method.

Dr. Walter Lathrop of the state hospital for the middle coal-field of Pennsylvania at Hazleton, writes:

> Our traumatic surgery consists almost entirely in the treatment of accidents sustained in and about the mines, and the question as to whether an anesthetic should be employed is answered in the injury itself, in most instances, and not entirely dependent on the judgment of the surgeon, for the majority of the cases are of such a nature as to demand immediate operation on admission.
>
> From the time the accident occurs until the patient is received in the hospital considerable valuable time elapses, the distance they are transported varying from one to ten miles, and it is only natural to suppose that many suffer excruciating pain and gladly submit to any course of treatment by which their suffering can be alleviated. It invariably happens that those severely injured beg to be "put to sleep," as they express it. With the fear of taking an anesthetic, so commonly encountered in non-traumatic surgery, eliminated, the depressant action of the anesthetic does not manifest itself so markedly, while the pain endured undoubtedly acts as a stimulus to the various nerve centers. These factors, acting as a unit, preclude to a great extent any danger in administering anesthesia, except in those cases in which exhausting hemorrhage has occurred or in profound nervous depression, for in this type it would be almost malpractice to attempt any local treatment without first endeavoring to combat the constitutional deficiency. An anesthetic is administered fearlessly in injuries of various parts. No discrimination is made as to the injured parts, following of course the rules mentioned above. For general anesthesia, our anesthetic of course is chloroform, preceded in all cases by a hypodermic injection of morphin, gr. ¼, and atropin, gr. 1/150, based entirely on its successful use covering a period of eight years. In extreme cardiac weakness ether is sometimes substituted. Ethyl chlorid is used largely in superficial work. Traumatic shock, unless it be of a very severe type, does not contra-indicate the employment of anesthesia, for it has been found that in many cases the circulatory and respiratory systems often return to a condition nearer normal while under the anesthetic; especially is this true if the function of either has been embarassed directly by the injury. Death from anesthesia, either sudden or a reasonable length of time after its use in traumatic surgery, we have not yet experienced.

Professor Tuffier of Paris says that ether is the anesthetic of choice, but that he uses chloroform in chest conditions and uses a local anesthetic only on the extremities, as fingers and toes. He advises waiting until the shock has disappeared before operation and thinks the mortality depends on the severity of the shock. He uses spinal anesthesia in treating fractures of the extremities.

Dr. John H. Gibbon of Philadelphia says:

> In the absence of shock, I do not see that trauma in any way affects the anesthesia, except in extensive injuries of bones or extensive injuries of fatty structures when I think that fat embolism of the lung may be aggravated by ether. Serious injury of the thorax, I think, renders the administration of an anesthetic more dangerous. As a rule, I employ the following sequence in producing anesthesia, morphin gr. ¼, atropin gr. 1/150, by hypodermic twenty minutes before the anesthesia is started, then ethyl chlorid followed by ether. Spinal and infiltration anesthesias are used where possible, if the general anesthetic is contra-indicated. Where I am obliged to operate in shock, as for instance in hemorrhage, I employ the same sequence as in other cases. Except for shock, I do not see that the anesthetic acts any differently in traumatic and non-traumatic cases.

Dr. George Tully Vaughan of Washington does not find that there is any marked *difference in anesthesia in* disease and in trauma. He prefers ether to any other anesthetic and thinks that even in minor cases a general anesthetic is preferable to local anesthesia and is not any more dangerous than as correspondingly large dose of a local anesthetic.

Dr. John Rogers of New York says that ether is the anesthetic in general use at Bellevue Hospital. He prefers nitrous oxid and oxygen for injuries of the extremities but thinks ether or chloroform is to be preferred to nitrous oxid in injuries of the head.

Dr. Charles K. Teter of Cleveland has made some experiments comparing nitrous oxid with ether and finds that shock-producing trauma is better borne under nitrous oxid. He finds that the blood-pressure remains higher under nitrous oxid, and in shock it rises, whereas under ether it usually falls. He has used nitrous oxid in something over 15,000 cases with only one death; and this was not due to the anesthetic.

Dr. Edward H. Ochsner of Chicago does not think that traumatism *per se* is an indication against the use of an anesthetic if properly given. He thinks that ether if properly given is almost devoid of danger; he prefers training a lay woman to give anesthetics. He thinks that the subject of anesthesia is really settled and that any further investigation can not add materially to our knowledge of the subject.

Dr. W. W. Grant of Denver prefers ether with oxygen. He advises against the administration of any anesthetic until the patient has reacted. He thinks there is "less shock and greater immunity from anesthetic" in head injuries than in other parts of the body.

Dr. J. D. S. Davis of Birmingham, says:

> Ether, I think, is the best anesthetic in shock in traumatic surgery. I have had no deaths from anesthetics in traumatic surgery. Ether is the safest anesthetic in fracture cases, internal injuries and rupture cases, especially where shock is present. In traumatic cases with shock, ether is not only more satisfactory and safer than chloroform, but as a rule, relieves the shock. In traumatic surgery, I believe that primary operation under ether is safer than waiting for shock to subside before administering the anesthetic. I have had very little experience with nitrous oxid gas and oxygen, but I believe it is the coming anesthetic in traumatic surgery, because it has marked advantage over ether in the relief of shock.

My personal experience has been confined principally to mine injuries, including injuries of the head, spine, extremities and trunk. It has been my good or ill fortune to operate on eighteen or twenty spinal injuries with very little benefit to the patients, as in most instances the cord has been torn in two; in one case I sutured the cord and my patient did well for about two weeks when he died from an ascending infection from the bladder; I have invariably used ether in these cases, after the patient had reacted. A few years ago I became interested in the use of stovain as a spinal anesthetic and found that it reduced the shock where the extremities were badly mangled and enabled us to operate earlier than where a general anesthetic was used.

325 Woodward Building.

THE COMPARATIVE DANGER OF ETHYL CHLORID AS AN ANESTHETIC *

HORATIO C. WOOD, JR., M.D.
PHILADELPHIA

Statistics are notoriously unreliable, and yet there are certain problems which can hardly be studied by any other method. A striking illustration of one of the causes which leads to the untrustworthiness of vital statistics is found in the recent paper by Miller[1] on ethyl chlorid anesthesia. In this paper Miller presents the statistics on 43,796 anesthesias with ethyl chlorid, in which there were 5 deaths. In the same paper, however, there are references to some 30 fatalities occurring during ethyl chlorid anesthesia, of which at least 20 are directly attributable to the anesthetic. These cases, however, could not be included in his table, because they were reported as isolated cases without any means of determining the corresponding number of anesthesias which had been produced with safety. Miller from his statistics places the mortality from ethyl chlorid anesthesia at 1 in 8,800 cases. McCardie[2] presents statistics of 9,711 cases with four deaths of which he was cognizant. Of these cases 2,000 (with no deaths) the personal experience of McCardie are included in Miller's table. It would seem, however, that it is only fair in attempting to reach conclusions as to the danger of these anesthesias, that McCardie's statistics, although they cover a comparatively small number of cases, should be added to those of Miller. If we do this we have statistics of 51,507 cases with 9 deaths, a mortality of 1 in 5,710. The statistics on ether and chloroform of Coates, Gould, Garree, Gurlt and others,[3] covering several million cases, give a mortality from chloroform of about 1 in 3,500, and from ether, 1 in 15,000. From the statistical standpoint, therefore, ethyl chlorid would seem to stand between ether and chloroform, but closer to the latter.

This conclusion, however, is unfair because the anesthesias by ethyl chlorid have practically all been of but a few minutes' duration, and the secondary dangers which occur as a result of prolonged anesthesia and which have caused a considerable bulk of the fatalities of ether and of chloroform do not come into consideration in the case of ethyl chlorid. Ethyl chlorid, on account of the quickness and fugaciousness of its action, enters into competition with nitrous oxid gas rather than with ether. Lee,[4] in reviewing the use of ethyl chlorid at the Pennsylvania Hospital, says that, in spite of the comparatively high mortality which has followed its use at that institution, it is "still being used for minor surgical procedures and dressing more painful wounds," and also as a preliminary to ether. Of twenty-two deaths reported by Luke,[5] 8 were in dental cases. It is evident, therefore, that the fair comparison for ethyl chlorid is with nitrous oxid when used for a few minutes only. If we set alongside of the commonly accepted mortality for the latter gas so used, 1 death in 1,000,000 anesthesias, and the figures for ethyl chlorid, 1 in 6,000, the danger of this agent is evident.

As remarked by Miller, the safety of an anesthetic is to be judged by two factors: first, the range between the amount required to produce unconsciousness and that required to kill; and second, the character of the signs which indicate approaching danger. As this author points out, the danger signals in ethyl chlorid anesthesia are such as may be easily overlooked by any except the most experienced anesthetizer. There is another element of danger which comes to light in studying the reports of the individual fatalities from ethyl chlorid, and that is the extraordinary suddenness of the end. In the great majority of these cases death has occurred from an anesthesia of less than five minutes; in one instance the patient was dead within half a minute from the beginning of the inhalation.

McCardie calls attention to the high mortality from this anesthetic in England as compared to the European continent, which he believes is due to the fact that it is habitually administered in that country by the "closed" method; a number of experienced anesthetizers are in accord with this view.

While I may perhaps seem unduly harsh in my condemnation of an anesthetic which has given good results in the hands of a number of anesthetizers of large experience, it is because of my profound conviction that the freedom with which this drug is being employed by inexperienced and untrained persons, with the idea that it is practically as safe as nitrous oxid, is little short of criminal. In this country, especially outside of large cities, it is being used habitually by dentists in connection with the extraction of teeth. This practice, I believe, is one which the medical profession should strongly condemn. The only possible advantage possessed by ethyl chlorid over gas, aside from the question of cost, is its portability. Such considerations, however, should not be allowed to stand for a moment as against the fact that ethyl chlorid is about 200 times as dangerous as nitrous oxid.

Simple Non-Operative Cure of Hemorrhoids.—J. Toth writes to the *Wiener medizinische Wochenschrift*, Nov. 19, 1910, to call attention to a simple means of keeping hemorrhoids under control, and finally curing them, by gentle, constant compression. This is accomplished, he says, by means of a rather loose pledget of absorbent cotton, not larger than a large pea, which is introduced into the anus between the internal and the external sphincters. Under the influence of the compression the varicose enlargement of the veins at this point retrogresses and the hemorrhoids become obliterated. The loose cotton pledget has several advantages over a solid device for the purpose: The anus does not behave toward the cotton as toward a foreign body, while the gentle compression day and night is scarcely perceived. The pledget does not have to be removed before defecation, as it is expelled with the stool. Systematic perseverance in its use is the main thing. Toth says that he has been successfully applying this simple measure for several years.

PREVENTION OF HEMORRHAGE IN PULMONARY TUBERCULOSIS BY THE ADMINISTRATION OF AUTOGENOUS VACCINES *

ROSWELL T. PETTIT, B.S.
Fellow in Pathology, University of Chicago; Bacteriologist, Ottawa Tent Colony
OTTAWA, ILL.

Discharge of blood from the mouth may be caused by heart disease, carcinoma, hemophilia, arteriosclerosis, vicarious menstruation, hysteria, aneurysm, bleeding gums, or nasal, pharyngeal, or gastric lesion, but the great majority of hemorrhages are from tuberculosis of the lungs.

Stricker[1] found 221 of 480 hemorrhages due to tuberculosis, and in 196 more this was probably the cause. Sée[1] (1884) says, "Aside from infectious diseases, hemophilia, and acute infections of the lungs (pneumonia, abscess, gangrene) we only know of two real causes of hemoptysis—heart disease and pulmonary tuberculosis."

The pathologic conditions preceding hemorrhage vary with the stage of the disease. In early cases it may be due to localized hyperemia in the lung induced by violent or long-continued exercise; or, more likely, due to weakening and erosion of small blood-vessels by the growth of tubercles. Early hemorrhages are always venous; in later stages hemorrhages arise from both the arteries and veins (Minor[1]). The connective tissue of the adventitia is more resistant to dissolution than the surrounding pulmonary tissue, and vessels stand out in the walls of cavities unsupported; on these unsupported vessels aneurysms develop and hemorrhage results with a weakening of the wall of the aneurysm and any slight rise in blood-pressure. That hemorrhage is due, in many cases, to rise in blood-pressure is seen in its relation to overexertion. Hemorrhage may also result as an oozing of blood from granulations lining old cavity walls.

The frequency of hemorrhage has been reported as between 30 and 80 per cent. De Renzi[1] says that hemorrhage occurs in one-third to two-thirds of his cases (1894), Fox[1] (1891) in 54 per cent, Aufrecht[1] (1905) in 26.4 per cent, Williams[1] (1887) in 57 per cent, Walsh[1] (1871) in 81 per cent. (Minor). In the 181 cases which I have studied the percentage is much less, 15.46.

The immediate causes of hemorrhage given by various authors are overexertion, straining at stool, blows on the chest wall, and other things that would cause an undue rise in blood-pressure. Excitement, worry, temper, etc., would act in the same way. Hot, damp weather favors hemorrhage. The systemic plethora of the premenstrual period and vicarious menstruation may be rare causes. The overfeeding of tuberculous patients not infrequently predisposes to hemorrhage. The importance of sex is slight. The season of the year has a marked influence on hemorrhage; the worst period of the year, in the vicinity of Chicago, being the summer, and the hot spells are especially dreaded. Epidemics of hemorrhages have occurred, however, at other periods of the year, frequently during the winter and spring. These, I believe, are due to epidemics of "colds," influenza, etc.

Fox[1] (1891) says that heredity is important, patients with a marked family history of tuberculosis showing the greater tendency. Age is also an important factor; hemorrhage is very rare in childhood, more common between the ages of 20 and 30, less common after 45, and rare in old age.

The influence of mixed infection on hemorrhage is not given by any of the authors I have consulted, but Flick concludes from the bacteriologic studies made by Ravenel,[2] Irwin, and himself that the pneumococcus is an important agent in causing hemorrhage. The influence which mixed infection may exert on the pathologic changes occurring in pulmonary tuberculosis is by no means definitely known. The bacteriologic examination of the sputum reveals but little in the majority of cases because so many of these secondary organisms are found under normal conditions living saprophytically on the mucous membranes in various parts of the respiratory tract. Some authors state that the bronchi in health are free from bacteria (Cornet[3]). Others assert that a great variety may be present even in health. Post-mortem bacteriologic studies of the lung have revealed but little. Streptococci, notorious as causing terminal septicemia, have been found in a majority of the cases examined. How are we to know whether they were present in the lung early in the disease or invaded as a terminal septicemia? The findings of most investigators in this field show the presence of the *Bacillus coli*, *Proteus vulgaris* and other post-mortem invaders, in addition to the pyogenic cocci and the diphtheria bacillus in the lungs examined. Organisms of secondary infection have been found in the blood-stream in a small number of cases, usually far advanced, and but a short time before death. Panichi,[4] however, reports that in three of four cases he recovered organisms of mixed infection from the blood-stream at least two months before death.

Prudden[5] (1894) was unable to produce cavities in guinea-pigs by the inoculation of tubercle bacilli alone. He was able to produce them, however, in tuberculous guinea-pigs by intratracheal injections of streptococci. Marmorek,[6] on the contrary, was able to produce cavities by injecting tubercle bacilli in conjunction with large quantites of strong tubercle toxins.

Webb[1] says that an irregular opsonic index to any of the secondary organisms is diagnostic of mixed infection. Wirth[7] examining twenty-five cases, found abnormal indices in cases showing no temperature and did not find irregular indices in cases showing high and irregular temperatures. He found serums giving a normal result at the time of drawing to show abnormal indices the following day. The normal index he considered as between 0.8 and 1.2. He found no change in the index to *Bacillus capsulatus*, *tetragenus*, *catarrhalis*, *Bacillus pneumoniæ*, *Bacillus coli*, or *subtilis*, but he found a variation to staphylococcus, streptococcus, pneumococcus, and influenza bacillus. The following were his results: influenza, 2 out of 17 examined; staphylococcus, 2 out of 17 examined; pneumococcus, 18 out of 24 examined; streptococcus, 6 out of 19 examined. I have taken the opsonic index to the pneumococcus, streptococcus and staphylococcus in 40 cases representing all stages of the disease, both active and inactive, and found an abnormal index in only one case. The index in this case was 0.75 and this was to the staphylococcus. This patient had an anal fistula in which the staphylococcus was present in large numbers. The normal index in both Wirth's report and my own was considered as between 0.8 and 1.2. Therefore I do not consider the opsonic index of value in the diagnosis of mixed infection in tuberculosis.

It is difficult to estimate the importance of mixed infection in tuberculosis at the present time. The experimental results are contradictory and the conclusions of investigators are at variance. Because of the atypical course of the disease, the rapid variations in temperature at irregular intervals, the fact that extensive infiltration may occur in a few days and disappear leaving areas of caseation or softening, I am convinced that organisms other than the slow-growing, persistent, slightly toxic, tubercle bacillus are concerned. Some authors have contended that practically all the damage to lung tissue is done by organisms other than the tubercle bacillus.

Weaver[8] has shown that injections of killed streptococci protects rabbits against subsequent injections of large numbers of living virulent streptococci. The work of Wright[9] and others has shown that injections of killed and attenuated bacteria have a protective effect against subsequent infection. This production of active immunity has been known for a long time and its importance in preventive medicine has been proved conclusively by Jennerian vaccination against small-pox, and Pasteur's vaccination against chicken cholera, anthrax and hydrophobia. It has been successfully employed against typhoid. Wright has collected statistics dealing in all with 49,600 individuals, of whom 8,600 were inoculated and showed a case incidence of 2.25 per cent. with a mortality of 12 per cent. In the remaining 41,000 uninoculated the case incidence was 5.75 per cent. with a case mortality of 21 per cent.

The data on protective inoculations against pyogenic infections are very meager, but the results that have been obtained in therapeutic inoculations against the gonococcus, streptococcus, staphylococcus, pneumococcus, etc., especially in chronic, subacute and localized infections, seem to show that injections of killed organisms hasten recovery and protect against relapse.

Webb[1] has used killed organisms against mixed infection in tuberculosis and has observed a protection in inoculated cases against influenza. Five patients inoculated against influenza with their own organisms, and eight inoculated against influenza with stock vaccines, all giving histories of repeated former attacks, escaped the epidemic. Preventive inoculations were not given in thirty-two cases, the patients denying that they ever had influenza, and fifteen succumbed to an influenza epidemic.

Since June 15, 1909, I have administered autogenous vaccine in thirty-one cases of pulmonary tuberculosis at the Ottawa Tent Colony. Of these thirty-one cases twenty-one were under observation two months or longer. Patients not under observation at least two months are not included in this report.

Vaccines were not administered as a protective measure, but therapeutically. It has been observed that during the fall and winter of 1909-10 hemorrhages have been less frequent than before. The class of patients, diet, exercise, sleeping conditions, and supervision were practically the same as in preceding years; the only new factor introduced into the treatment was the autogenous vaccines. It occurred to me that possibly the injection of vaccines against the organisms of secondary infection had a protective action against tissue dissolution and hence against hemorrhage.

The vaccines administered in all cases were autogenous. They were prepared by taking carefully selected particles of sputum and washing by whipping vigorously in several changes of sterile water with sterile forceps. The washed sputum was then introduced into about 10 to 15 c.c. of either plain bouillon or a medium made up of 1 part of sterile beef serum and 3 parts of bouillon. This was incubated at 37 C. for twenty-four or forty-eight hours, at which time a moderately thick growth had developed. The beef serum mixture appeared to have no advantage over the plain bouillon. The growth was then examined for bacteria, and the relative number of cocci, in pairs, tetrads, clumps and chains were noted. Allen[10] says the proportion of the various organisms thus grown is approximately the same as when introduced. More recently I have been using large blood-agar slants for the cultivation of bacteria from the sputum. The emulsion of bacteria was shaken vigorously for ten or fifteen minutes, centrifuged at high speed for from forty-five seconds to one and one-half minutes, depending on the density, and the supernatant homogeneous emulsion decanted into another tube.

The number of organisms was then estimated by Wright's method. This is done by taking up one volume of 1.5 per cent. solution of sodium citrate in a capillary pipette, then equal volumes of blood and bacterial suspension, mixing thoroughly on a slide, drawing up into the pipette and then making four slides by placing a small drop on each and drawing out in a thin smear by dragging the edge of another slide over it. These were stained with methylene blue and the erythrocytes and bacteria present in fifteen fields in each of the four slides were counted. An estimation of the number of organisms present in a cubic millimeter of the emulsion was then calculated. The number of erythrocytes in 1 cubic millimeter was considered as 5,000,000; the number of erythrocytes in the number of fields counted is to the number of bacteria as 5,000,000 is to x. By multiplying by 1,000 the approximate number of organisms in 1 c.c. was obtained. This is a long and laborious procedure, so I tried counting the bacteria in a blood-counting chamber in the same way the blood-count is made. To do this it was necessary that the organisms be stained. I used a fresh, carefully filtered solution of gentian violet or Unna's methylene blue. I drew some of this stain into the pipette, a volume of the bacterial suspension, to be estimated, then more stain, and finished my dilution with either distilled water or salt solution. The pipette was shaken vigorously, several drops blown out and a small drop placed in the Thoma or Turck counting-chamber and covered with an ordinary thin coverslip. The coverslip used in blood-counting is too thick to use with the oil immersion lens. The chamber was then set aside until the organisms had settled: it usually takes about one to six hours, depending on the diluent used and the size and number of the organisms present. Whether the organisms have all settled out or not is easily determined by focusing on the lines of the chamber and then raising the lens through several planes and looking for organisms in suspension. The bacteria are well stained and easily distinguished. If there are confusing particles of dirt present, a weak alcoholic solution can be used as a diluent; this gives a very clean slide and the bacteria are easily picked out. The method is very simple and rapid, and, I believe, more accurate than Wright's method. In the preparation of vaccines during the past four months, November, 1909, to March, 1910, I have used this method exclusively.

[10] Allen: Vaccine Therapy and Opsonic Treatment, Ed. 2, Philadelphia, 1908, Blakiston's Son & Co.

The organisms were killed by heating to 60 C. for forty-five minutes, either before or after counting, and sterility was insured by inoculating a tube of broth or blood-agar from the heated suspension. The suspension was then placed in a sterile bottle of brown glass and a drop of strong phenol or compound solution of cresol added.

The size and frequency of the dose administered depended on the condition of the patient. In afebrile patients in fairly good physical condition comparatively large doses, 200 to 500 million, were given, at intervals of seven to ten days. In febrile cases with the patients *in poor* physical condition, doses of 25 million were administered every second or third day for several doses and then increased to 50 and 100 million. When doses of 100 million or more were given the interval was lengthened to from five to ten days. In all cases considered in this report, at least three doses were administered. The number of hemorrhages occurring in all classes of patients under observation for at least two months, from June 15, 1908, to March 1, 1909, are compared with the number of hemorrhages occurring in all classes of patients under observation for at least two months, from June 15, 1909, to March 1, 1910. The number of hemorrhages occurring in all classes of patients receiving vaccines during the latter period is compared with the number of hemorrhages occurring in cases not receiving vaccines during the same period.

TABLE 1.—HEMORRHAGES BETWEEN JUNE 15, 1908, AND MARCH 1, 1909, NO PATIENTS RECEIVING VACCINES

Class.	Cases, No.	Hemorrhages, No.	Hemorrhage, Per Cent.
Incipient	42	6	14.28
Moderately advanced..	44	11	25
Advanced	13	1	7.7
Far advanced........	1	0	....
Total	100	18	18

TABLE 2.—HEMORRHAGES BETWEEN JUNE 15, 1909, AND MARCH 4, 1910, ALL PATIENTS, THOSE RECEIVING VACCINES AND THOSE NOT RECEIVING VACCINES

Class.	Cases, No.	Vaccinated, No.	Hemorrhages, No.	Hemorrhage, Per Cent.
Incipient	16	3	0	0
Moderately advanced..	30	4	5	16.6
Advanced	24	11	4	16.66
Far advanced........	11	3	1	9.1
Total	81	21	10	12.34

TABLE 3.—HEMORRHAGES BETWEEN JUNE 15, 1909, AND MARCH 1, 1910, PATIENTS RECEIVING VACCINES

Class.	Cases, No.	Hemorrhages, No.	Hemorrhage, Per Cent.
Incipient	3	..	....
Moderately advanced..	4	..	....
Advanced	11	1	9
Far advanced........	3	..	....
Total	21	1	4.7

TABLE 4.—HEMORRHAGES BETWEEN JUNE 15, 1909, AND MARCH 1, 1910, PATIENTS NOT RECEIVING VACCINES

Class.	Cases, No.	Hemorrhages, No.	Hemorrhage, Per Cent.
Incipient	13	..	....
Moderately advanced..	26	5	19.2
Advanced	13	3	23.1
Far advanced........	8	1	12.5
Total	60	9	15

It is seen from the tables that the total number of hemorrhages during the same period of time and during the same seasons of 1909-1910 is about 50 per cent. less than the total number of hemorrhages occurring during a corresponding period in 1908-1909.

From June 15, 1909, to March 1, 1910, in *patients* receiving vaccines the percentage of hemorrhage *is only* one-third of the percentage in patients *not receiving* vaccines. All patients were under exactly the same conditions of housing, feeding, and medical supervision. While it is not admissible to draw definite conclusions from such a small number of cases, the results seem to be indicative and will justify the administration of autogenous vaccines in a larger number of cases as a protective measure. A report will be made next year.

I wish to thank Miss Elizabeth Peck and Miss Elizabeth Byrne for assistance in the preparation of vaccines and the determination of opsonic indices.

TINCTURE OF IODIN FOR THE UMBILICAL CORD

Joseph S. Lewis, M.D., Buffalo, N. Y.

The increasing use of iodin suggested to me its application to the freshly severed umbilical cord. The tincture, as is well known, tends to form a dry iodin-impregnated scale or scab over any moist surface not giving *off* a purulent discharge, such as a clean varicose ulcer or a freshly sutured wound. The treatment to be described was tried on several infants with satisfactory results. In one case the cord was found mummified and separated on the fourth day, the granulated surface healed to a small dry scab within the same week. Others averaged ten days to two weeks for the entire process. Iodism was not observed. The technic used is as follows:

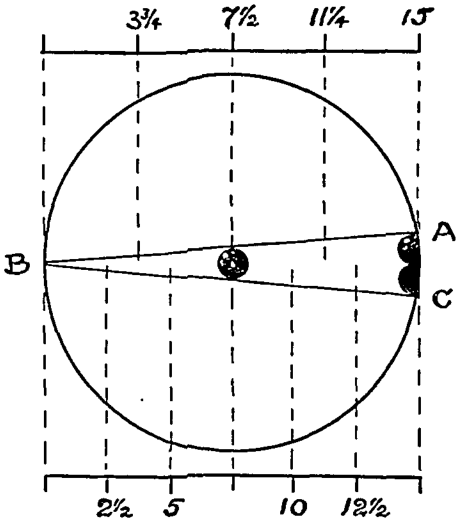
As soon as the cord is cut and tied, blood and vernix caseosa are wiped off with a sterile pledget. The stump is then painted with the *official* tincture until deeply stained: especially the cut end, the ligature, and the line of attachment. Due care should be taken to avoid the epidermis beyond the line of union with the cord. After the bath, dry sterile gauze or cotton is packed about the stump and held with the usual binder. In case the dressing becomes soiled or moist it is changed at once. After the cord falls off the granulating or denuded surface remaining is painted as before, and the dressing is reapplied. The advantages of the method consist in simplicity, increased rapidity of drying, and the penetrating bactericidal property of the drug.

471 Virginia Street.

A SIMPLE METHOD FOR THE MEASUREMENT OF BLOOD-CELLS

PHILIP ATLEE SHEAFF, M.D.
PHILADELPHIA

In the microscopic examination of blood it sometimes becomes desirable for purposes of comparison and classification to know, with some degree of accuracy, the size of certain cells. The method about to be described is simple, fairly accurate, and can be used by anyone who cares to expend a little patience in adapting the eye-piece of his microscope for the procedure, and when once accomplished, having a permanent fixture.



Sketch illustrating a simple method for the measurement of blood-cells. View of field, with available measurements in microns, when the radius is divided into halves and thirds. Spun glass A B C giving black line effect and forming gauge.

It consists in arranging two pieces of spun glass across the diaphragm of the eye-piece so that an acute angle is formed, the apex of the angle coming exactly to one border of the field which is the opening in the diaphragm. The other ends of the spun glass are separated sufficiently so that at the margin of the field they just enclose two normal red blood-cells, one above the other, in apposition, thus making approximately 15 microns.

The spun glass may be obtained by heating a piece of glass stirring-rod in the flame of a Bunsen burner and quickly pulling the ends apart after removing from the flame. A piece of this minute thread may be easily handled by a silver probe, the end of which has been warmed and touched to a small piece of paraffin, a little of the same substance being previously distributed over the diaphragm at diametrically opposite points.

When the final satisfactory adjustment of the spun glass has been made a small piece of paraffin is gently placed over the ends of the same and the heated end of the probe quickly "solders" them permanently in place.

A normal red cell of 7.5 microns will just fit between the lines when in the center of the field, and it requires but a glance to locate the position of a cell in relation to the apex or base of the triangle when it is placed so that both lines touch its edges.

A cell so placed can easily be recognized as being in the middle of the right half of the field, or the middle of the left half of the field, or in the outer, middle, or inner thirds of either half of the field, giving a scale of microns marked in the sketch, which for blood work is particularly appropriate; and a scale for comparison in other cases which may suggest themselves.

4008 Baring Street.

A CASE OF HAIRY TONGUE

M. LEON, M.D.
MT. OLIVE, ILL.

I wish to report a case of "hairy tongue" which came under my observation and treatment a few weeks ago.

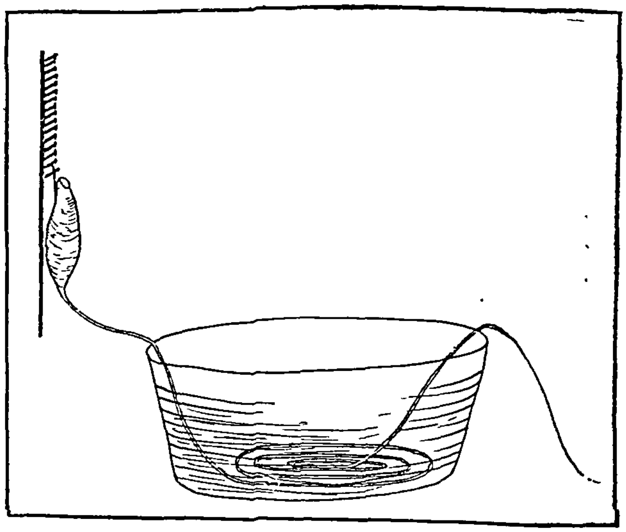
History.—The patient, Mrs. W., aged 75, informed me that she had been suffering from chronic indigestion for the last five years. On examination of her tongue I found a black, velvety coating strongly resembling a mass of long, fine hair. The coating was located in the center of the tongue on the papillæ filiformes. A scraping of it was put under the microscope for examination and was found to contain epithelium and an immense number of mycelia. The papillæ filiformes were somewhat hypertrophic.

Treatment.—After applying for several days a strong solution of potassium chlorate, pure hydrogen peroxid, etc., without marked benefit, I scraped off the coating under local anesthesia and applied a 10 per cent. alcoholic solution of mercuric chlorid. This application was repeated daily for two weeks, with the result that the coating has entirely disappeared.

A SIMPLE METHOD OF RECTAL FEEDING OR PROCTOCLYSIS

EBEN C. HILL, M.D.
First Lieutenant Medical Corps, U. S. Army
MADISON BARRACKS, N. Y.

The excellent results obtained in the treatment of peritonitis by proctoclysis, and the number of cases demanding nutrient enemas, have resulted in the devising of various forms of more or less elaborate apparatus for introducing fluids slowly and continuously into the rectum at a constant temperature. For hospital work or when refined instruments can be used any of these give admirable results. But in certain cases occurring outside of hospitals a simple and readily improvised method is sometimes of value.



Protoclysis apparatus, consisting of an ordinary rubber enema bag, long rubber tube and rubber catheter, a large pan containing hot water in which is coiled the rubber tube for maintaining the proper temperature of the saline fluid; also a simple device for regulating the height of the bag. The apparatus may be used also for rectal feeding.

In a cancerous condition of the stomach demanding rectal feeding, and in a recent case of duodenal ulcer, I successfully used the following device, and its simplicity may recommend it in emergencies in which a more elaborate apparatus is not obtainable:

> Two-inch nails are driven into a small board at intervals of an inch for about two feet. This board when tied to the bed or nailed to the wall gives a means of lowering or raising the enema bag. About fifteen feet of medium heavy tubing is attached to the end of an ordinary two-quart enema bag, and a small rubber catheter is joined to the end of this tube. Near the edge of the bed is placed a pan containing two or more gallons of warm water, the temperature of which is about 100 F. Into this pan the tube passes and is coiled so that about twelve feet of it is immersed in the water. A heavy rubber such as is found in the lavage tube is needed in order that the tubing may not twist itself to the surface as happens with inferior or light weight tubing. The pan should be near the patient so that the rubber pipe and catheter may have only a short distance to pass to the rectum.
>
> The enema bag is then leveled so that the flow shall be about twenty drops a minute. The normal salt solution or nutrient fluid, being warmed to about 99 F. when put into the bag, regains any heat lost during the injection in passing through the coils of tubing in the warm water. As a consequence the fluid enters the rectum at a fairly constant temperature. Once an hour an attendant can add a little hot water until the temperature is "a little warmer than the hand." Three gallons of water in an ordinary dish pan at a temperature of 100 F. in a room where the temperature is 72 F. loses only about four or five degrees in half an hour or longer.

Therapeutics

HYPOSECRETION OF THE THYROID

The disturbances caused by an insufficiency of the thyroid gland will, of course, depend on whether the secretion is diminished or entirely absent. Also, it is logical to believe that certain elements of the thyroid secretion may be diminished while others are normal, or it is even possible that some elements may be increased while others are diminished. Such a supposition will account for the manifold indications both of hypersecretion and hyposecretion. The conditions caused by diminished secretion may be enumerated as follows:

Chlorosis
Amenorrhea
Obesity
Goiter
Eczema
Hysteria (depressant forms)
Vomiting of pregnancy
Eclampsia
Epilepsy
Melancholia
Slow growth in children
Cretinism
Adiposis dolorosa
Lipomatosis
Myxedema
Senility

The theory of hypothyroidea, or a subsecretion of the thyroid gland, has been advocated by some for many years, and now the condition has been generally accepted as clinically recognizable, even when present in small degree. If the secretion is entirely absent in a young child, a cretin results. If it is seriously defective, there is slow and stunted growth. If it is present in larger amount but still much insufficient, juvenile obesity is present, with a phlegmatic disposition, slowed pulse, and a delayed puberty. If there is an undersecretion at puberty (and this occurs most frequently in young girls) we have amenorrhea, perhaps chlorosis, and often peculiar nervous crises, even epileptic attacks. The typical symptoms of hypothyroidea are best recognized and studied in the adult female. If there is absolute absence of secretion myxedema develops. A normally diminishing secretion, such as occurs after 45 or 50 years of age, is shown by symptoms, the most evident being the addition of flesh, especially deposits of fat, a slowly increasing blood-pressure, and a gradual development of connective tissue in various parts of the body. If this secretion diminishes normally as age advances into old age, the skin begins to lose its nutrition and dries and wrinkles, with a tendency to the occurrence of eczemas.

PRINCIPAL USES OF THYROID

The *absence of menstruation*, after it has once developed, without pregnancy or acute or chronic disease, generally points to a diminution of the thyroid and ovarian secretions. If the patient is anemic, iron and ovarian extract should be the treatment. If the patient is not very anemic and tends to put on weight, thyroid is the treatment. The dose of thyroid should be small, not more than 3 grains of the dried extract once a day.

There has never been a satisfactory explanation of the condition of *chlorosis*. For some reason these patients do not metabolize the iron of their food. Large doses of iron always cure these patients. Arsenic does the same, possibly from its stimulation of the thyroid gland, possibly from some unexplained antiseptic action. Sometimes some of the laxative inorganic salts, in small doses, act satisfactorily. Sometimes small doses of thyroid are efficient. It is generally true that if these girls begin to menstruate normally the disease disappears, and thyroid is the best emmenagogue that we possess.

Infantile obesity is best modified by small doses of thyroid, and if recognized early the condition may be inhibited. The disturbance in metabolism that is most frequently improved by thyroid is *obesity*. Thyroid will probably cause loss of weight in every instance provided a sufficient amount is given, but at the same time there is a great nitrogenous loss, and there is always the danger of causing disturbances due to an increased amount of thyroid in the blood, some of which may be serious. It can cause faintness and loss of strength, and a debility which may not be recovered from in a considerable length of time. If weight is being added, especially in women, after 45, small doses of thyroid may prevent it. If the fat is already present, it may take considerable dosage to reduce it. The large doses which were once used for this purpose are not justifiable, and a patient under thyroid treatment for obesity should be very carefully watched, and the administration should cease as soon as any unpleasant symptoms appear. When weight is put on in younger life, especially in women, thyroid is the most efficient treatment, and the dose required is generally not large. The value of combining such treatment with a diet free from sugar and with a diminished amount of carbohydrates, and with physical exercise, should not be overlooked. The dose of thyroid should be 0.20 gm. (3 grains), at first three times a day for a week, then twice a day for another week, and after this once a day will probably be sufficient. To be sure that the thyroid is active, 0.25 gm. (4 grains) of sodium iodid should be administered once during each twenty-four hours. The patient may not begin to lose weight for at least two weeks, and after that some weight should be lost every week, and patients may lose weight even after the treatment has been stopped. The loss of two or three pounds a week should be considered sufficient and satisfactory. If the excessive weight is hereditary, or has persisted for years, the fat will again return on cessation of the treatment, and in these patients great loss of weight will not be caused by the treatment without the necessity for more thyroid being administered than is safe.

If undesirable fat begins to be deposited before the age of 40, unless there is a marked family tendency to such excessive weight, the thyroid is probably undersecreting. If such deposits of fat occur on the hips. over and under the clavicles, on the upper arms, around the breasts in women, with a feeling of oppression, dyspnea on exertion, and especially if menstruation has ceased, the diagnosis is absolute, that the thyroid is secreting insufficiently. If this condition just described further develops, *adiposis dolorosa* is in evidence, the only difference being that of degree and that the fatty parts are painful. The thyroid is always found to contain a large amount of connective tissue and to be subsecreting in this disease. In the rare instances of general and localized *lipomatosis* the thyroid is probably not perfectly active, although other signs of its inactivity may not be present. Thyroid will always improve the condition of the skin even if it does not inhibit the advance of the disease.

An ordinary *goiter* represents an excess of colloid material or cystic degeneration. The portion of the gland so affected is diseased and undersecreting, but the rest of the gland is generally secreting a sufficient amount for the organism so that symptoms referable to the thyroid are not present. A primary thyroid hyperactivity or hyperplasia may have been present before the colloid excess occurred.

Whether the tendency for the residents of certain regions to develop is due to an absence of sufficient iodin in the water or to some other cause has not been determined. In some regions almost all the women (women being the more susceptible) have enlarged thyroids. But few of them probably, however, show symptoms of thyroidism. Strangers, especially women, going to these regions often readily and quickly develop goiters. Removal from these regions and the administration of small doses of iodid generally quickly cause improvement. Most such patients are very susceptible to thyroid feeding, and will often quickly show symptoms of hyperthyroidism under its administration. Boiling the drinking-water in these regions has sometimes seemed to inhibit the enlargement of the thyroid gland.

Simple goiters are more frequently operated on than formerly, probably because all operations are becoming more popular, but perhaps these large glands caused greater discomfort and disturbance than was supposed. The operation is not as serious when a portion of these glands is removed as when the patient has Graves' disease, but it can never be termed a simple operation. Sudden heart failure may occur during the anesthesia, and any other operation that it is necessary to perform on a patient who has goiter should be done under the most careful anesthesia.

Many *eczemas* of early childhood are often incorrigible until minute doses of thyroid are administered. These are especially the type that occur around the orifices of the body, and when little fissures or cracks in the skin occur. The troublesome eczemas of old age often will not heal with local treatment until small doses of thyroid are added to that treatment. Sometimes the results obtained by such treatment of these patients is most satisfactory

Hysteria of the melancholic depressant type where there is apathy, unwillingness to talk, and general depression, may be improved and cured by the administration of small doses of thyroid. The border-line between this kind of hysteria and beginning melancholia is hard to determine, but the cerebral stimulation caused by thyroid will sometimes prevent the development of insanity. Whether actual melancholic insanity is benefited by thyroid is doubtful, but it certainly is a treatment sufficiently logical to be tried in every case. Dr. A. H. Peabody (*Boston Med. and Surg. Jour.*, Aug. 14, 1910), has shown that 75 per cent. of patients who die with mental disease have abnormal thyroids.

There have been various and many suppositions as to the cause of the persistent *vomiting of pregnancy*. It is certain that if the vomiting persists the patient develops an acidosis, and this cause alone may continue the condition or actually cause death. Whether it is purely reflex or whether there is a metabolic poisoning of the system of which vomiting is a consequence, it seems certain that any method that allows the mother to metabolize her food better, and eliminate the nitrogen excretory products properly, will be of benefit to her. Whether there is often or occasionally a subsecretion of the thyroid during the early months of pregnancy when vomiting is so likely to be in evidence is not known, but many instances have been reported in which the administration of small doses of thyroid has improved such a serious condition. It is certain that the thyroid will increase the nitrogenous output in the urine. It is also certain that the thyroid should hypersecrete during pregnancy. If it does not do so it is acting abnormally, and the vomiting of pregnancy may be an indicator of such subsecretion.

It is certainly advisable, when a woman has given birth to one or more children who have shown subthyroid activity, to administer to her thyroid gland substance during her next pregnancy. Such treatment is logical, and has been successful in producing healthy children. If it is inadvisable to give small doses of thyroid to a pregnant woman or if its results are unsatisfactory, small doses of iodid may be substituted, when it is decided that the patient's own thyroid is not secreting properly.

Many obstetricians now believe that one of the best treatments for *eclampsia* is thyroid. In instances in which it is successful the poisoning is probably a nitrogen poisoning, and eclampsia can occur without serious kidney defect. When a pregnant woman is found to have signs of subsecretion of the thyroid she certainly is in danger of eclampsia at parturition, and the previous administration of thyroid is certainly indicated. A dose of three grains a day, at least during the last month of pregnancy, is advisable. If eclampsia has developed, 1 gm. (15 grains) of thyroid should be given at once and repeated in two hours.

Epileptic attacks developing during some disturbance of menstruation, whether at the time of puberty or at the time of the menopause, and especially if repeated only at the times of the menstrual periods, just before or just after, or at the time when the menstrual period should occur and does not, shows that the cause has something to do with the thyroid. The thyroid gland hypersecretes normally at and before menstruation; if it does not do so, something in the system cannot work as perfectly physiologically. In the kind of epilepsy just described thyroid is the treatment. It should be administered in small doses, 3 to 5 grains, daily (the size of the dose depending on the symptoms of the physiologic action of the thyroid), during the interval between the periods. When the attack is expected, for a day or two before, bromid treatment may be added. If the thyroid acts unpleasantly, causing palpitation or loss of weight, it need not be given throughout the whole four weeks of the interval, but may be omitted during the first two weeks. Many instances are on record in which this kind of epilepsy has been cured by such treatment.

More or less complete insufficiency of the thyroid in adults causes *myxedema*. This is a rare disease in men, and occurs in more than 80 per cent. of all cases in women, and mostly in those who have borne children. It would seem from such statistical facts, that the gland is inclined to excessively atrophy because it has previously been stimulated, in women, from the periodicity of its increased secretion on account of menstruation, and from its overwork during pregnancy. Myxedema in its full development is, in this country, a rare disease. Partial myxedema, hypothyroidism, is frequent and often unrecognized. In myxedema there are all kinds of nervous disturbances and circulatory disturbances, joint and muscle pains, headaches, itching and tingling. The skin may be dry and harsh. Later, deposits of fat generally occur all over the body. The face is round, full, dull and apathetic. There is a great deposition of mucin in the tissues of the skin giving a feeling of edema but with no pitting. The taste is impaired and perverted. The patient may complain of a bitter, a sour, or some other disagreeable taste, and the digestion is impaired. The patient also may complain of noting a disagreeable odor. There is sluggish mentality, the memory is impaired, and the general disposition may be entirely abnormal to the individual. The patient sleeps a great deal, even in the daytime. There may be hallucinations, even bordering on melancholia. The temperature is generally subnormal, the pulse slow, and the blood anemic, although there may be a tendency to hemorrhages, either from the uterus, the nose, the gums, the bowels, or into the skin. One patient about 50 years old, during the incidence of the menopause, had an attack of profuse bleeding from the nostrils, ears, gums, intestines and bladder, almost to exsanguination. She was cured by thyroid feeding after every other known treatment had been administered and failed.

In myxedema the external genitalia are swollen, amenorrhea is generally present, and the sexual desire is lost. The urine often shows albumin, and may show casts. If the disease is not arrested by proper treatment death is likely to occur from progressive anemia, kidney insufficiency or cardiac weakness. The disease is slow in its progress, but death may occur in five or six years.

The almost invariably successful treatment is thyroid; all of the above symptoms disappearing. The dose should not be large, but if for any reason the treatment is rapidly pushed, the patient should be in bed lest sudden heart failure occur from the large doses of thyroid. As soon as the patient improves, the dose should not be large; a dose of 3 grains of the dried gland substance a day is sufficient, and even this may subsequently be given but every other day, or even less frequently. Sometimes the thyroid gland of such a patient may be stimulated or may recuperate, or perhaps a supernumerary thyroid may develop so that active thyroid medication is needed only intermittently.

In *operative myxedema* in which the thyroid gland has been removed totally, or so much has been removed that the secretion of the remaining portion is insufficient, or in some instances of true myxedema, in which the patient cannot live without continued thyroid treatment, transplantation or implantation of thyroid gland tissue into various organs of the body has been tried, sometimes with success. This same implantation has been tried in cretins, and there are records of success. The younger the patient, the more successful, perhaps, is the treatment, but the whole subject of such transplantation is as yet purely experimental.

Hypothyroidea and partial myxedema, easily recognized when the physician once becomes used to looking for it, is hardly recognized at all by the majority of practitioners. Any one, two or three of the symptoms above described as characteristic of myxedema may be present in a patient, and be due to a subsecretion of the thyroid. It is hardly necessary to enumerate these conditions. Suffice it to say that the unusual addition of weight, irregular fatty deposits, drying of the skin, slowing of the pulse, sleepiness, mental apathy and stupidity, gastro-intestinal disturbances that are unexplainable by organic disease, an abnormal desire for sugar, urinary defects in evidence with some of these other conditions, all point to subsecretion of the thyroid. The treatment is either small doses of thyroid, or an iodid, or both. Premature falling of the hair, or the hair becoming brittle and readily breaking, irregular and unexplainable skin eruptions, especially of the dry, scaly varieties, may many times be improved by judicious thyroid feeding. Sometimes there are joint pains, and in some instances arthritis deformans has been thought to be caused by disturbed thyroid activity, as in these instances administration of thyroid has been of marked benefit. This, however, is not generally the case.

In *cretinous children* the thyroid is either absent, or, if present, contains a small amount of colloid material or is cystic, and there is almost entire absence of thyroid secretion. The curative action of thyroid in cretinism is a demonstrated fact, and the sooner the diagnosis of cretinism is made, the greater the amount of success which will attend the use of thyroid. Unfortunately the diagnosis of cretinism can rarely be made until the child is from 6 months to a year old, and if there is not total absence of thyroid secretion, an infantile myxedema cannot be determined until the child is 2 or 3 years old. If a cretin or a patient with infantile myxedema is not treated until he is several years old the results of such treatment are much less satisfactory. The dose for an infant is not more than .065 gm. (1 grain) of the official thyroid powder, two or three times a day. If the cretin is older, the dose may be larger. Its unfavorable action would be shown by increased cardiac rapidity and loss of appetite. Its favorable action is shown by a diminution of the myxedema; in other words, the puffiness of the skin becomes less, and there is an actual loss of weight. The mental powers should increase, and the hair, nails, teeth and bones should normally grow. The thyroid feeding, as soon as improvement has positively taken place, should then be slightly diminished, and a smaller dose given daily for months and perhaps for years. If unpleasant symptoms of thyroid action occur, the thyroid should be stopped for a week and then again begun at a smaller dose.

UNCLASSIFIED USES OF THYROID

Thyroid has been used with success in some instances of hemophilia and purpura hemorrhagica, as well as in the irregular hemorrhages of the menopause.

It has been used in chronic rheumatism as well as in arthritis deformans, and has many times been successful in gouty rheumatism, especially where the attacks showed a general disturbance of metabolism, such as at one time an asthmatic attack, at another an indigestion attack, and at another a typical gouty joint attack. Small doses given for a considerable time are often successful in this kind of metabolic disturbance.

Sometimes thyroid acts as a diuretic, and it certainly is an antidote to nitrogenous poisoning in insufficient kidney action. Even uremic convulsions are sometimes kept in abeyance by the administration of thyroid. During a uremic attack the dose of thyroid should be large, as 10 grains of the dried extract three time a day. Such treatment sometimes apparently prevents convulsions, and in some instances seems to aid in saving life.

Thyroid has been used in various skin diseases, sometimes with success. The indication seems to be to stimulate extra secretion of the skin. If there is an acute inflammation or hyperemia, thyroid would not be indicated. Conditions in which it has been successful are the dry chronic eczemas, sometimes in psoriasis, ichthyosis, and in some instances scleroderma.

If not otherwise contra-indicated, whenever there is excessive connective tissue development in any organ—in other words, a sclerosis or a cirrhosis—a small dose of thyroid daily is of benefit. The dose should be so small that it could not cause evident signs of its physiologic activity. In many of these instances small doses of iodid, given daily for long periods, may be of as much benefit.

Some clinicians have certified to, and even proved, in certain instances, the value of thyroid in inhibiting or causing resorption of carcinomatous growths. This is especially true of uterine carcinoma. The majority of investigators, however, have not found this treatment successful.

THE ADMINISTRATION OF THYROID

Unless thyroid is administered in large doses to combat an intoxication or toxemia, as in puerperal eclampsia or uremia, a therapeutic dose should cause no evident symptoms. In other words, if thyroid is to be administered continuously for its continued physiologic effect it should give no more symptoms than does the normal thyroid secretion. The amount administered per day should be small enough to represent the amount that would reach the blood from a normal thyroid gland. This means in the course of twenty-four hours very little thyroid secretion. If the amount that we administer causes symptoms of thyroidism such as palpitation, hot flashes, headache and sleeplessness, or any of the other symptoms mentioned as symptoms of Graves' disease, the amount given is excessive and should be diminished. It should also be recognized that the administration of thyroid for a short time, even in small doses, will doubtless stimulate a temporarily sluggish thyroid gland to more perfect action. Consequently, a given dose not at first too large becomes gradually too large, and later not needed. It also seems to have been proved that small doses of iodin, as represented by an iodid, is a stimulant to a sluggish thyroid, and should perhaps be the treatment first given when there are evidences of hyposecretion of the thyroid. It has been shown that the thyroid may become active, if it obtains a little more iodin. If 0.10 or 0.20 gm. (1½ to 3 grains) of iodid a day does not soon render the thyroid more active, then thyroid substance should be given. The signs of excessive thyroid administration which are not as self-evident as those above mentioned are loss of appetite, loss of weight, tendency to perspire too freely, and too low blood tension.

Large doses of thyroid may cause nausea, dizziness, and, if quickly absorbed, faintness. There is probably no direct acute poisoning from thyroid, although large amounts have been known to cause convulsions and even death from shock, *i. e.*, by the toxic effect on the heart and the enormous vasodilator effect, as has been seen in operations for Graves' disease when the thyroid has been too much manipulated and a large amount of its secretion has been squeezed into the circulation.

The treatment of acute thyroid intoxication would be the hypodermatic or intravenous use of epinephrin or other suprarenal vasopressor substance, the administration of atropin and strychnin. Possibly good treatment would be a venesection from one arm while physiologic saline was transfused into the other arm.

Contra-Indications.—Any symptoms similar to those of Graves' disease should ordinarily prohibit the use of thyroid. Also, if during the administration of thyroid excessive nervousness, sleeplessness, palpitation, and loss of weight occur, the administration should be stopped. Ordinarily a poor condition of the circulation and a soft and weak pulse should prevent its use. Serious nervous and cerebral excitation should also ordinarily prevent its use.

Official Preparation.—Glandulæ thyroidæ siccæ, desiccated thyroid glands, is a yellow powder prepared from the thyroid glands of sheep. It has a disagreeable, meaty smell, and is partially soluble in water. This preparation of course contains the active principle of the thyroid gland, but its activity depends on the amount of iodin content, and this is variable. The dose varies from 0.03 gm. (½ grain) to 1 gm. (15 grains), depending on the frequency and the object for which it is used. Thyroid may also be obtained in tablets which vary in size and strength.

Unofficial Preparations.—Iodothyrin is an artificial preparation recommended by Baumann to represent thyroid substance, and occurs as a brown powder, which contains 9 per cent. of iodin and 0.5 per cent. of phosphorus. This preparation has not been found so active or so efficient as thyroid gland substance, and consequently should not be used when thyroid is indicated, provided thyroid substance can be obtained. The dose is slightly larger than that of the above official preparation.

Various antithyroid preparations may be obtained. These are of course indicated when there is too much thyroid secretion. One preparation is termed "thyroidectin," and is prepared from the blood of thyroidectomized animals. It is a reddish-brown powder, and may be obtained in capsules each of which contains 5 grains. The dose is one to two capsules, three times a day.

Moebius' antithyroidin is a serum obtained from the blood of thyroidectomized animals, the dose of which is from 2 to 10 drops, three times a day.

The milk of thyroidectomized goats may be administered fresh from the animal.

RELATIVE IMPORTANCE OF BOVINE AND HUMAN TUBERCLE BACILLI IN HUMAN TUBERCULOSIS

Since Koch's sensational announcement in 1901, to the effect that human and bovine tuberculosis are not identical, and that the occurrence of bovine tuberculosis in man is so rare that no special protective measures are indicated with respect thereto, numerous investigations have been made in regard to the relationship of bovine and human tubercle bacilli. An especially valuable study of this question has been made recently in the research laboratory of the department of health of New York City.[1] Park and Krumwiede point out that it is of great importance to know as definitely as possible the actual percentage of bovine infection in man, because if bovine tuberculosis occurs to an appreciable extent steps must be taken to prevent the milk-supply, especially of large cities, from carrying tubercle bacilli. In order to contribute to the solution of the problem in question, the New York investigators have studied carefully the types of bacilli obtained from a large number of unselected cases of different types of tuberculosis and representing well the average conditions of exposure to infection. An enormous amount of work has been done and the results secured are of great value. The most improved technical methods were used.

A Merry Christmas to All! Let no one slight the ancient custom of mirth and cheer; but if there be any whose existence has grown stale—who have ceased to renew the fresh wonder of life by sharing its simple joys with children and the childlike—who have forgotten or ignored that wisdom, deeper than the learning of the schools, which makes life worth while—to such we wish a Merry Christmas in double and triple measure. This is the day of all others to observe what Stevenson called the most underrated duty in the world—the duty of happiness. Beauty for ashes, the oil of joy for mourning, the garment of praise for the spirit of heaviness—a Merry Christmas!

Park and Krumwiede conclude that tubercle bacilli isolated from man fall into two groups, the human and the bovine. Each type presents peculiar cultural and biologic characteristics, most of the cultures grouping themselves around two extremes. There is no conclusive evidence in favor of any rapid change of type. The actual number of cases examined is 436—the largest number so far covered in a single investigation; 297 occurred in persons over 16 years of age—278 being pulmonary—and of these cases only one, a case of renal infection, gave bacilli of the bovine type. Children between 5 and 16 years furnish 54 cases, nine being of the bovine type so far as the bacilli go. Eighty-four cases were in children under 5 years, and of these twenty-two had bovine bacilli.

These results are in general harmony with results obtained previously. Their cases, added to cases similarly studied and recorded in literature, give a total of 1,040 cases of human tuberculosis from which pure cultures of tubercle bacilli have been obtained and identified as either bovine or human in type. Dividing these 1,040 cases into three groups with respect to the age of the patients, we find that Park and Krumwiede place 686 cases in the first group, which comprises the patients of 16 years and over, and nine of these patients gave bacilli of the bovine type; in the second group, which covers the ages between 5 and 16, are 132 cases, thirty-three with bovine bacilli; and in the third group, which includes the children under 5, are 120 cases, fifty-nine of which are of the bovine bacillary type.

If not a single case of pulmonary tuberculosis have bacilli of undoubted bovine type been found; there are 568 cases of pulmonary tuberculosis in the first group and of these one case figures as furnishing bacilli of questionable bovine type.

The larger proportion of the cases with bovine type consists of the infections of the abdomen and of the glands of the neck. In 15 per cent. of the fatal cases in children under 5 bovine bacilli were found.

It thus becomes evident, from the results which have been briefly outlined here, that the bovine type of the tubercle bacillus plays a significant and by no means a negligible part in the etiology of tuberculosis in children and that the efforts at prevention of this disease clearly must include the sources of bovine bacilli.

WILLIAM PRYOR LETCHWORTH, REFORMER AND PHILANTHROPIST

In Mr. William Pryor Letchworth, who has just passed away at the age of eighty-eight years, the medical profession has lost a helper of unusual spirit. He stood between science and that helpless portion of the population that needs state care, and taught the people of New York State how to spend their money so as to give the best possible scientific and humanitarian aid to its dependents.

In his early life a business man, he earned a fortune, and all those who were associated with him shared his prosperity. Then, retiring from business, he devoted nearly fifty years of his life to practical philanthropy. Seldom does one find such business acumen, such scientific grasp of conditions and such brotherly love combined as salient traits in one man; and these, combined with a love of the fine arts, and the power to attract kindred souls, formed a character whose qualities strengthened the fibers of our civic life.

Mr. Letchworth was for ten years, from 1878, president of the State Board of Charities, and from that time until his death every branch of the work has felt the effect of his intelligence and persistent effort, and out of his wise administration have grown changes for the better in the care of the poor in county houses, the blind, orphan and destitute children, and juvenile delinquents.

He had always been keenly alive to the suffering and wrongs of the insane and epileptics as they were cared for in years gone by in public institutions. In order to understand the subject thoroughly, he spent two years in Europe, visiting institutions and hospitals in every country, and when in 1886 he was appointed chairman of a commission to select the site for an asylum for the insane in northern New York, he not only chose what experts pronounce to be the finest site for such an institution in this country, but suggested many ideas which led to improvement in the comfort of the patients.

Perhaps the work with which his name will always be most intimately associated is Craig Colony for Epileptics, which grew practically out of his ideas. Imbued with the ideas of Bielefeld, Germany, where the epileptic lives a useful life in a village of epileptics, Mr. Letchworth guided the state in establishing in the Genesee valley that remarkable community, composed wholly of epileptics and their helpers, who live in a model colony, doing farm and garden work, housework, brick-making, and learning and practicing the trades needed in village life.

The value of a work like Mr. Letchworth's lies in its power of coordinating other men's work. He was like the expert critics employed by great business concerns to detect wasteful and inefficient methods, and substitute time-saving and labor-saving systems. The philosopher, who criticizes the lack of coordination in the loose business of life, does great service to his generation; but rarely does one meet a philosopher who leads the way to practical reform. This was what Mr. Letchworth did for his state in every public enterprise that had to do with the unfortunate. He found out how to remedy existing evils, and then applied his brains and his fortune to making needed reforms go through.

"THERE'S A REASON"

Grape-Nuts is a breakfast food and Postum Cereal is a substitute for coffee, both manufactured by the Postum Cereal Company, Battle Creek, Mich. This concern has applied the "patent medicine" methods of advertising to the exploitation of food products. Are you threatened with appendicitis? Use Grape-Nuts! Have you "heart trouble and dizzy headaches?" Try Postum Cereal! Do you suffer with "loose teeth?" Eat Grape-Nuts! And so on. Not, of course, that the recommendations are so crudely made as those just given. In fact, like most "patent medicine" advertising, the most dangerous and mendacious claims are those made by implication. For instance, the company does not say frankly that Grape-Nuts is a "brain food"; not at all. Instead: "No one, until the inventor of Grape-Nuts, thought of making a special food for the brain and nerves." It is probable that the Postum Cereal concern has in its advertisements given greater publicity to more pseudo-scientific twaddle than was ever before inflicted on a long-suffering but patient public. But "There's a Reason." It has sold the goods!

Five years ago *Collier's Weekly* refused to accept the advertising of the Postum Cereal Company on the ground that the products were being exploited by "patent medicine" methods if not actually as "patent medicines." In July, 1907, that publication called attention to the following statement made by the Postum concern:

> "It is a practical certainty that when a man has approaching symptoms of appendicitis, the attack can be avoided by discontinuing all food except Grape-Nuts and by properly washing out the intestines."

Collier's characterized such claims as "lying and, potentially, deadly lying." The manufacturer, as a "come-back," had advertisements printed all over the country accusing that publication of attacking his product "for the purpose of forcing him to advertise." As this practically amounted to charging *Collier's* with attempting to blackmail the Postum Cereal Company into advertising, the owner of that weekly at once brought suit for libel. The verdict that has just been returned in Mr. Collier's favor is said to be the largest ever rendered in a libel suit in this country.

Collier's is to be congratulated. It is a common thing for the manufacturers of "patent medicines" and similar products, when their preparations or methods are criticized, to intimate that the journals exposing them have had an ulterior motive in so doing. It is seldom, however, that such manufacturers are so commercially tactless as to make their charges definite, and in black and white.

The Postum Cereal Company, which is said to spend a million a year in advertising, is attempting to offset the result of the verdict by an advertising campaign in which the actual cause of the suit is carefully kept in the background while the points regarding the products themselves are greatly magnified. As a matter of fact, the products, as such, did not enter into the case at all, the methods of exploitation and the claims made for them being the essential matter.

Why does not the Postum Cereal Company explain that the Food and Drugs Act has made it necessary for it to modify the claims made on the Grape-Nuts package? Why does it not mention that some of its testimonials have been rewritten and paid for? Why does it carefully conceal the fact that the "famous physician" who wrote the Postum testimonial is a "poor old broken-down homeopath, who is now working in a printer's establishment" and who received ten dollars for it? These are points that the public is entitled to know so that it may place a just estimate on the worth of the testimony offered. Why is the Postum Cereal Company silent? Well, again: "There's a Reason."

THE DEPARTMENT OF AGRICULTURE AND ITS WORK

When a Department of Agriculture was proposed, nearly twenty-five years ago, exactly the same objections were raised to its establishment that are now being made to the organization of a federal department of health, except that, as no great fortunes were being made by selling nostrums and cure-alls to or for cows, horses, pigs and chickens, the opposition to the establishment of a department of agriculture did not come from quacks, fakers and swindlers. With this exception, however, the objections were the same: the rights of the state were being invaded; the government was taking up work which did not belong to it; the project was simply an excuse for the expenditure of large sums of money; the people did not approve of it; its establishment would be of no value, etc., etc. The manifold and highly valuable activities of the United States Department of Agriculture at present constitute a striking refutation of the objections made to its establishment. A copy of Circular No. 721 of the Department of Agriculture shows the bulletins, circulars and reprints issued by the Department in the single month of November, 1910. These publications are of interest not only to the farmer but also to the farmer's wife and children, and in many cases, to the entire community. In the list are found such topics as these: some insects injurious to forests; life-history of the codling-moth; field studies of the crown-gall and hairy-root of the apple-tree; experiments in blueberry culture; insects which kill forest trees, character and extent of their depredations and methods of control; directions for the use of black-leg vaccine; a review of some experimental work in pig-feeding; the tapeworms of American chickens and turkeys; tuberculosis of hogs, its cause and suppression.

Twenty-five years from now, when the United States shall have taken its place with other civilized nations in public health work and when the federal government has come to recognize officially the fact that the life of a human being is as much a matter of government concern as the life of domestic animals, we shall probably have a national Department of Health issuing a monthly list of publications with titles something like these: some parasites injurious to school children; life-history of the typhoid bacillus; field study of infantile poliomyelitis; experiments in child culture; bacteria which kill factory employees, character and extent of their depredations and methods of control; directions for the use of typhoid vaccine; a review of some experimental work in infant-feeding; the tapeworms of American citizens; tuberculosis of children, its cause and suppression.

Such work will bring even more benefit to the people in the next twenty years than the splendid work of the Department of Agriculture has secured in the past twenty years.

Current Comment

OPTOMETRY BILLS IN STATE LEGISLATURES

Legislatures in thirty-two states will convene the first week in January. In about eighteen of these states, according to the statements made in "optometry" publications, bills providing for the appointment of boards of examiners in "optometry" will be introduced, on the plea that they are intended for the protection of the public against incompetent and untrained spectacle fitters and will supplement medical practice acts. The plan of campaign usually followed by the promoters of these bills is to secure, before the bill is introduced, the endorsement of as many physicians as possible, and then to assert before legislative committees that the bill "has the endorsement of the leading physicians of the state."[1] If the real purpose of the bills was to require a higher standard of training and education among *opticians*, there would be no objection to them, provided schools of instruction for opticians were properly supervised. Experience in every state in which these bills have become laws, however, has shown that as soon as the "optometrist" received the sanction of the state, in the form of a license, he immediately placed himself before the public as a "Doctor of Optometry" and as one competent, not only to correct errors of refraction by lenses, but also to treat any diseases of the eye, no matter what the cause. With the development of this business a number of purely commercial "schools" have sprung up, many of them diploma mills, giving "correspondence courses." These "colleges" are turning out large numbers of "graduates." Instead of being a movement for the protection of the eyesight of the people, as claimed by its supporters, it has become a campaign for the recognition, by the state, of a horde of uneducated, untrained men, who, under the title of "Doctors of Optometry" claim to be competent to treat all diseases of the human eye—a work which to-day requires not only a complete course in modern medicine, but special and additional training as well. This pernicious legislative crusade should be opposed by physicians everywhere and the real facts should be placed before the legislatures and the public. Especially should physicians refrain from signing petitions or endorsing bills without realizing their true import. This caution is particularly necessary at present in view of the activity of the advocates of these measures.

THE NEW CHILDREN'S JOURNAL

An announcement was recently made in these columns concerning the new journal to be published by the American Medical Association—the *American Journal of Diseases of Children.*[1] The initial number is now on the press and will be issued promptly on the first of the year. In its articles, in the character of its editorial board and in its mechanical features, this journal will be the equal and a worthy companion of the other special journal published by the American Medical Association, *The Archives of Internal Medicine.* It is not a commercial enterprise—it is merely another effort of the Association to advance scientific medicine, and especially scientific medicine in America. Already an encouraging number of subscriptions have been received for the new journal. One progressive physician in sending in his subscription says: "I take great pride in the *Archives of Internal Medicine,* in The Journal of the American Medical Association and in other publications coming from your press, and I want your baby book from the start." In order that his file of the new journal may be complete, every physician who contemplates taking it should likewise begin his subscription with the first issue, and thus avoid the annoyance of ordering back numbers, which are not always easily supplied.

MEDICAL ADVERTISING IN LAY JOURNALS

As has often been said—and truthfully—printer's ink is the life-blood of quackery. Debar the advertisements of medical charlatans from newspapers and magazines and these frauds would become a negligible evil. To physicians who know the falsity of the quack's claims, the cruelty of his promises and the fraudulence of his methods, it is an ever-present wonder how reputable and honest publishers can accept the advertising of the nostrum monger and the quack. In many cases there is no doubt that newspaper and magazine owners purposely close their eyes to the evils of this kind of advertising copy because of the enormous revenue it brings in. In many more cases, however, the advertisements are accepted in good faith and in the belief that the claims made, while doubtless exaggerated, are not more so than those made by advertisers in other lines of business. These remarks are prompted by looking at two pages from the *Agricultural Epitomist* sent us by a correspondent. On one of the pages is a half-page advertisement of as bold and impudent a medical swindle as often appears. It deals with "Professor Samuels," whose methods and claims are discussed in the Pharmacology Department[1] of this issue. On the other page is an editorial comment under the heading "Advertising Talks" in which the following statement occurs: "You know advertised articles are all right because they have stood the test—and besides, the advertisers are backed by your publisher's guarantee." To physicians it may seem unthinkable that a rational human being could honestly be willing to "guarantee" such a fake as the Samuels "treatment" of all diseases "through the eye." Yet we believe it is done in good faith. Samuels doubtless submitted to the publisher a bushel or two of testimonials and to the lay mind a testimonial carries with it a conviction that no amount of argument can overthrow. We believe that in this case, as in many other similar ones, what the publisher lacks is judgment rather than principle.

RECOMMENDATIONS OF THE SURGEON-GENERAL OF THE NAVY

The annual report of the Surgeon-General of the United States Navy, recently issued, forms a volume of nearly 200 pages and reviews the work of the Bureau of Medicine and Surgery for the past year. The substance of the report is found in the twenty-one recommendations which form its conclusion. Many of these relate to purely technical matters connected with the administration of the Navy, but some of them are of general medical and scientific interest. Among the recommendations are: that the ability to swim well be required hereafter as a prerequisite for officers and men in the Navy and Marine Corps; that a naval medical reserve corps be established; that dentists commissioned as officers of the lower grades be provided; that venereal prophylaxis, as practiced in Asiatic and Atlantic fleets, be enforced throughout the entire service, both ashore and afloat; that vaccination against typhoid fever be extended to the entire personnel of the Navy under the age of 50 years; that the bubbling-spring device for drinking-fountains be adopted for the entire service; and that Congress be asked for an appropriation to build two suitable hospital ships. The report contains much interesting material, including condensed reports from naval medical officers in all parts of the world.

Differential Diagnosis of Syphilis and Psoriasis.—During the course of an eruption of psoriasis it is not unusual to find lesions on the penis, glans, and scrotum, in men, and on the vulva in women. The lesions in these situations are atypical owing to the moisture of the parts, the scales being soft and fragile, not hard, dry, or scaly, as in ordinary psoriasis. These lesions may be mistaken for mucous syphilides, but the presence of patches of typical psoriasis on the knees, elbows, etc., will settle the diagnosis.—C. F. Marshall, in the *Practitioner.*

Medical News

ARKANSAS

The New Sanatorium.—The new Arkansas Tuberculosis Sanatorium, Booneville, is nearly filled to its capacity. At the beginning of the month there was room only for ten additional patients. The capacity of the institution is 74.

Suggest Removal of Hospital.—The board of trustees for the State Charitable Institutions will, it is reported, recommend to the governor and legislature the removal of the State Hospital for the Treatment of Nervous Diseases from Little Rock.

County Election.—At the annual meeting of the Prairie County Medical Society, held in Hazen, Dr. James C. Gilliam, Des Arc, was elected president; Dr. H. T. Rhodes, vice-president; Dr. James Parker, Devall Bluff, secretary, and Dr. William W. Hipolite, Devall Bluff, treasurer.

Antituberculosis Society Organized.—The Antituberculosis Society of Jefferson County was organized at Pine Bluff, December 1. J. L. Caldwell presided at the meeting and Ephraim Frisch acted as secretary. Drs. John S. Jenkins, William S. Stewart, William H. Blankenship, all of Pine Bluff, make up the committee for medical aid.

GEORGIA

Ambulance for Hospital.—The Atlanta *Georgian* gave a benefit performance at the Grand Opera House, December 23, the proceeds of which are to be applied to the purchase of an automobile ambulance for the Grady Hospital.

Physician Imprisoned.—For failure to pay the fine of $1,000 imposed on him in the Chatham Superior Court for illegal prescription of cocain, Dr. Walter W. Lee, Savannah, is said to have been committed to jail, November 25.

Money for State College.—Citizens of Augusta have subscribed $27,845 for new buildings for the Medical College of Georgia, Augusta, and for the hospital connected with the institution. The citizens have agreed to raise $50,000 toward the new buildings. A mass meeting was held in Augusta, December 11, to promote this worthy object.

Personal.—Dr. Howard J. Williams, Macon, has been appointed a member of the advisory board of the Southern Health Conference.——Dr. Thomas J. Collier Griffin, who was operated on recently in Atlanta, is reported to be greatly improved.——Dr. John P. Atkinson, Milledgeville, has been appointed councilor of the Sixth District Medical Society, vice Dr. T. Ellis Drewry, Griffin, resigned.

ILLINOIS

Hospital Site Donated.—Walter Farwell, Lake Forest, has donated to the recently organized Lake Forest Hospital Association an acre of land for a site for the hospital to be erected next spring.

Personal.—Dr. George M. French, Peoria, has been appointed supreme medical director of the Court of Honor, vice Dr. James E. White, deceased.——Dr. Robert C. Bradley, Peoria, has been reelected physician of Peoria County.——Dr. E. E. Nystrom has been named assistant physician of Peoria County.

State Board and Anterior Poliomyelitis.—The September issue of the Bulletin of the State Board of Health is devoted to the consideration of acute poliomyelitis, and includes articles by Dr. Israel Strauss, New York City, on "Pathology;" by Dr. Simon Flexner, New York City, on "Experimental Poliomyelitis;" "A Review of the Literature of 3,523 Cases," by Dr. Frank E. Coulter, Omaha; "Acute Poliomyelitis," by Dr. J. S. Fowler, Edinburgh, Scotland; "Surgical Treatment of Infantile Paralysis," by Dr. Max Herz, Sydney, Australia, and "Reports of Epidemics," by Drs. John M. Armstrong, St. Paul; Colin K. Russel, Montreal, and C. A. Anderson, Stromsburg, Neb.

Chicago

Personal.—Dr. Frank Allport is spending several weeks in New York and other eastern cities studying the work done in the various eye and ear hospitals.——Dr. Oscar C. Willhite has resigned as superintendent of the Cook County Institutions.

Dr. Holt in Chicago.—Dr. L. Emmett Holt, professor of diseases of children in the Medical Department of Columbia University, New York City, gave the annual address before the Chicago Pediatric Society, December 17, on "A Study of 300 Cases of Acute Meningitis in Infants and Young Children."

Resolution on Illinois State Board of Health.—The secretary of the Illinois State Board of Health recently requested the Chicago Medical Society to investigate the charges which had been made against the state board. The council decided that it had no official jurisdiction over the State Board of Health or its members and adopted the following resolution:

> *Resolved*, That it is the sense of the council of the Chicago Medical Society that any official action on its part on the question of the attacks made on the state board would be undignified and unjustified by the powers of this body, as well as an implied reflection on the state board, which would be unwarranted by any evidence thus far submitted against said board.

INDIANA

Charges Against Physician Dismissed.—The State Board of Medical Examination and Registration, at its meeting in Indianapolis, December 6, dismissed for want of sustaining evidence, an affidavit filed against Dr. George M. Freeman, Shoals, in which he was charged with criminal practice.

Prevention of Ophthalmia of the Newborn.—A number of physicians of the state met December 15, at the office of Dr. John N. Hurty, secretary of the State Board of Health, and decided to support a bill requiring compulsory treatment of the eyes of all infants at birth by physicians and midwives. The draft of a bill for that purpose was intrusted to a committee composed of Drs. John N. Taylor, Crawfordsville; Moses S. Canfield, Frankfort; E. Grove Anthony, Indianapolis, and George F. Keiper, Lafayette.

Antituberculosis Propaganda.—The Indianapolis Board of Health, to arouse interest in the scientific methods of prevention of tuberculosis, arranged a mass meeting, December 12. Dr. Charles O. Probst, Columbus, secretary of the Ohio State Board of Health, delivered the principal address, illustrated with stereopticon views, which showed the different stages of the malady, methods of stamping out the disease, and also illustrations of the open-air school rooms which are in successful operation in many large cities. The mayor presided and addresses were delivered by Dr. Charles S. Woods, city sanitarian, and others.——The Indiana Branch of the American Red Cross Society has built several cottages at the Indianapolis City Hospital Tuberculosis Colony, and similar cottages in other cities in the state, and has also assumed charge of twenty-five individual tuberculosis cases.

MARYLAND

Baltimore

Well-Known Chemist Dies.—Mr. Louis Dohme, head of the firm of Sharp and Dohme, manufacturing chemists, died in Baltimore, December 12, from neuritis, aged 72. He was a graduate of the Department of Pharmacy of the University of Maryland.

The Johns Hopkins Fund.—The Johns Hopkins Fund now amounts to $610,495. In order to secure the $250,000 offered by the General Education Board of New York, it is necessary to increase this amount to $750,000 by January 1. The money raised is intended to meet the expenses of new buildings, and the removal of the institution to the surburban site at Homewood.

New Staff of Bayview.—The reorganization of the Medical Department of Bayview will take effect January 1. Dr. Thomas R. Boggs has been appointed physician-in-chief; Dr. Arthur M. Shipley, surgeon-in-chief; Dr. Gordon Wilson, physician-in-chief of the Tuberculosis Hospital; Dr. H. D. Purdon, physician-in-chief of the Hospital for the Insane, and Dr. Milton C. Winternitz, pathologist-in-chief.

Personal.—Dr. Caleb W. G. Rohrer has been elected a member of the Royal Society of Arts, London.——Dr. Thomas R. Boggs has resigned as resident physician of Johns Hopkins Hospital and Dr. Frank J. Sladen has succeeded him. Dr. Franklin Webb Griffith, first assistant gynecologist, has resigned and has been succeeded by Dr. John A. Sperry.——Dr. William J. Schmidt has been appointed assistant bacteriologist to the health department, vice Dr. Frederick V. Beitler, Halethorp, resigned.

MISSOURI

Acquitted of Assault.—Dr. Thomas J. Massey, Lockwood, charged with assault on a stockman of that place, was acquitted by a jury, December 2.

Adopts Firework Ordinance.—An ordinance has been passed by the city council of Kansas City prohibiting the use of fireworks in that city except at public exhibitions which are to be regulated under special permits.

Drinking Cups to Go.—The Board of Education of Kansas City, at its regular meeting, December 1, voted to abolish drinking cups in the ward schools. Bubbling fountains are to be installed to take their place.

Seek New Location for Tuberculosis Hospital.—Because of the inadequate supply of drinking water and the absence of sewerage facilities at the Buchanan County Farm, the county court has decided not to permit the location of the proposed tuberculosis hospital at that place. The president of the local antituberculosis society has been advised of the decision.

St. Louis

Hospital Completed.—The directors of the Barnard Free Skin and Cancer Hospital (St. Louis Skin and Cancer Hospital) announce that the new hospital has been completed, and that formal dedicatory exercises and inspection were held December 20.

Vaccine Virus Pure.—The report of the city bacteriologist and Dr. George Dock of Washington University states that the investigators examined forty-five tubes of vaccine virus, and found nothing to justify the charge that three cases of tetanus among school children had been due to the virus.

St. Louis Medical Society Election.—The annual election of the St. Louis Medical Society, November 25, resulted as follows: president, Dr. Robert E. Schlueter; secretary, Dr. Frederick C. E. Kuhlman; councilors, Drs. Carroll Smith, John McH. Dean and Joseph Grindon, and delegates to the state association, Drs. J. Henry Amerland, William W. Graves, George Homan, Cyrus E. Burford, Vilray P. Blair, Richard H. Fuhrman, Robert M. Funkhouser, Albert F. Koetter and Clarence M. Nicholson.

KENTUCKY

Personal.—Dr. Dunning S. Wilson, director of the Louisville Tuberculosis Dispensary for three years, has been elected to succeed Dr. A. M. Foster as medical officer of the tuberculosis sanatoria of Louisville at Hazelwood and Waverly Hills. This will place Dr. Wilson in control of the entire tuberculosis work of the city.——The following physicians of Paducah have been elected to office: Dr. H. P. Lynn, city physician; Dr. R. L. Fisher, meat and milk inspector, and Drs. Benjamin F. Bradbury and James T. Reddick, members of the board of health.

New Vital Statistics Law.—The new vital statistics law for Kentucky goes into effect January 1. Dr. W. Lucian Heizer, New Haven, has been appointed state registrar with headquarters at Bowling Green. Announcement has been made of the appointment of registrars for the various magisterial districts in Jefferson County. Dr. William E. Gary, the milk and dairy expert of Louisville, now connected with the city health department, will be the Louisville registrar. Dr. Benjamin W. Smock, county health officer, will have general supervision over the various registrars in the county.——Undertakers will hereafter receive burial permits from the registrar instead of from the health office as formerly. The registrar will receive 25 cents for each permit issued.——Physicians will receive 25 cents for each birth and death return.——County registrars will report at stated intervals to the state registrar, who will file the reports with the county clerk, to be kept in a fire-proof vault in his office. The county clerk is to receive a fee of 50 cents for each certified copy of a birth or death certificate. Registrars must deposit fees with the county treasurer, who will make payments once a year, by order of the fiscal court, on a voucher to be made out by the state auditor.

NEW YORK

Personal.—Dr. Clayton K. Haskell, surgeon-in-chief of the State Soldiers' and Sailors' Home, Bath, resigned, December 10.——Dr. Bradley F. Many, Port Jefferson, while making a professional call early in the morning of December 5, narrowly escaped death from exposure in a blinding snowstorm.

Health Lecturers Appointed.—State Health Commissioner Eugene H. Porter has appointed Dr. H. L. Wheeler of New York and Dr. W. A. White of Phelps as lecturers and consultants on oral hygiene to the State Department of Health. Drs. Wheeler and White with the medical officers of the state department will deliver a series of lectures throughout the state on various subjects pertaining to public health.

New List of Reportable Diseases.—The list of diseases that should be reported to the State Department of Health has been amplified and now includes the following: anterior poliomyelitis, anthrax, bubonic plague, cancer, cerebrospinal meningitis, cholera, diphtheria, hydrophobia, leprosy, measles, ophthalmia neonatorum, pellagra, pneumonia, scarlet fever, small-pox, tetanus, pulmonary or laryngeal tuberculosis, typhoid fever, typhus fever, whooping cough and yellow fever.

New York City

Personal.—Dr. Abraham Jacobi has received the honorary degree of M.D. from the University of Bonn, from which he obtained his first degree fifty-nine years ago; he has also been elected an honorary member of the Medical Society of Berlin on the occasion of its semi-centennial celebration.——Dr. Eugene L. Fisk, medical director of the Provident Saving Life Assurance Society, has been elected secretary of the organization.

Verdict Against Physicians.—An unusual case has just been heard before the Queens County Supreme Court, where action was brought against Drs. Pedro Francko and T. Grover de la Hoyde for performing an unauthorized autopsy on the body of a woman who died in St. Joseph's Hospital. The action is said to have been undefended and the jury rendered a verdict of $8,000 damages. It is stated that this is the first case of its kind tried in this state.

Hospital Bureau of Standards and Supplies.—The executive committee of this organization has presented the first annual report for the fiscal year ended September 30, 1910. This bureau was established under an agreement to which at the present time about fourteen of the largest hospitals in the city are parties. The object of the bureau is standardization and savings in the purchase of hospital and institutional supplies. The result of their first seven months' work confirms the soundness of the principle on which this organization was founded, namely, that standardization and combination in purchasing are of benefit to hospitals as well as in the business world. Very considerable savings have been effected on purchases made under agreements negotiated by the bureau. As time goes on and more institutions enter the membership, the usefulness of the bureau will become more evident. The committee confidently recommends the bureau to hospitals which have not already become affiliated. There is also a non-resident membership contemplated for hospitals outside of the city of New York.

NORTH CAROLINA

Personal.—Dr. William P. Ivey, Lenoir, was seriously injured in a runaway accident, December 8.——Dr. Buxton B. Williams, Greensboro, has had plans prepared for a three-story sanitarium.

The Betterment of Professional Conditions.—The State Board of Health and the State Board of Medical Examiners have organized a joint committee which is conducting a vigorous campaign for the betterment of professional conditions in the state. Dr. Richard H. Lewis, Raleigh, and Dr. George G. Thomas, Wilmington, represent the State Board of Health, while the State Board of Examiners is represented by Drs. Lewis B. McBrayer, Asheville, Benjamin K. Hays, Oxford, and James L. Nicholson, Richlands. Dr. McBrayer is secretary of the joint committee. An active canvass is being made to secure additional enactments providing for higher educational requirements of prospective students of medicine, the repeal of the clause in the present medical law which permits licensing of illiterate doctors for "limited districts," and increased appropriations to render more efficient the work of the State Board of Health.

OHIO

Returned from Europe.—Drs. Henry J. Gerstenberger and Harry B. Kurtz, Cleveland, have returned from Europe.——Dr. L. Loring Brock, Washington Court House, who has been in Europe for several months, sailed for home, December 10.

Personal.—Dr. Paul Bethards, Toledo, has been elected fleet surgeon of the Interlake Yachting Association.——Dr. Claude E. Hoover, Edgerton, has been appointed surgeon for the Lake Shore System at Cleveland.——Dr. John Costello, Sidney, has been selected as superintendent of the new tuberculosis hospital at Lima for Shelby, Allen, Auglaize, Mercer and VanWert Counties.——Dr. John C. George, first assistant physician at Dayton State Hospital, has resigned and will practice in Lima.——Dr. David Gillard, Port Clinton, has resigned as local surgeon for the Lake Shore System, and has been succeeded by Dr. Howard M. Montgomery.——The office of Dr. Ezra Burnett, Delphos, was damaged by water in a fire, December 2.——Dr. John J. Thomas has been appointed a member of the health board of Cleveland, vice Dr. Edward F. Cushing, resigned.——Dr. Ira E. Seward has succeeded Dr. Henry Baldwin as health officer of Springfield.

Ill and Injured.—Dr Clifford T. Okey, Columbus, is seriously ill in Mount Carmel Hospital with pneumonia——Dr David M. Smith, Newark, slipped on an icy pavement, December 3, breaking his right leg above the knee——Dr. John W Alexander is reported to be seriously ill at his home in Newark——Dr Renwick H. Montgomery, Youngstown, is reported to be critically ill as the result of cerebral hemorrhage——Dr P Letherman, Outville, sustained severe cuts on the head in a collision between his buggy and another carriage at Pataskala, December 3——Dr August Schumacher, Hamilton, who has been seriously ill with ptomain poisoning, is reported to be convalescent——Dr Elmer C Radenbaugh, West Salem, who underwent operation in Wooster City Hospital a few weeks ago, has recovered and resumed practice——Dr Upton M Carnes, Canton, is said to have been adjudged insane and ordered to be committed to the Massillon State Hospital

The Oxford Liquor Case—Dr Hugh M Moore, banker and druggist of Oxford, charged by the president of Miami University with having sold the liquor which figured in a Thanksgiving poker party given by students, is said to have been found guilty in the mayor's court, and fined $50 and costs The court found no fault with the defendant for having a prescription for liquor nor for having it filled in the store *in which he was part owner* The court held that the violation of the law was in the defendant having filled the prescription when he was not a druggist or pharmacist within the meaning of the code, which gives the following definition "one who has practiced pharmacy for a period of four years, or has received an equivalent training or has been examined by the State Board of Pharmacy of Ohio" The defendant's testimony was to the effect that the registered pharmacist employed in the store was absent when he filled the prescription A motion has been filed for a new trial.

Cleveland

Dance for Charity—From a ball in the Colonial Club St Vincent's Charity Hospital, Cleveland, received over $5,000

Endowment for Medical Library—By the will of the late Dr Rosenwasser, a bequest of $10,000 was left to the Cleveland Medical Library. The proceeds are to be used in purchasing medical books and periodicals Dr Rosenwasser also left his library for the use of the association

Agreement Regarding Milk—Because farmers who have had milk refused by one city have been accustomed to ship it to another city, the departments of health of Cleveland Cincinnati, Pittsburg, Columbus, Youngstown, Lorain and Akron, cities which draw their milk from the same territory, have agreed that no milk or cream refused by any city represented because of faulty conditions at the dairy or any violation of the conditions imposed by the codes of these cities, shall be accepted by any of the other cities represented

Robb Memorial Services—Memorial services were held recently for Mrs Isabel Hampton Robb The plan announced was to provide a memorial hall to serve as headquarters of the various organizations for trained nurses of the city, containing an auditorium, library offices, restaurant and living accommodation Dr Charles F Hoover announced that the $6,000 already subscribed will be used as a fund for lectures to be delivered before nurses by medical men, and for popular lectures on hygiene for mothers and children Dr William H Welch, Baltimore, paid a glowing tribute to the memory of Mrs Robb who he said, probably did more than any other one person in reforming and organizing the profession of trained nurse.

Cincinnati

Honan in Cincinnati—Dr J H Honan, Bad Nauheim, Germany, formerly president of the Anglo American Medical Society, Berlin addressed the Cincinnati Academy of Medicine recently on 'Weak Heart, Its Causes and Treatment"

Personal—Dr E Otis Smith has been appointed cystoscopist and Dr O V Huffman, curator to the Cincinnati Hospital——Dr Edward A Fox, for many years staff physician of the Hamilton County Infirmary, has resigned

Department of Health Reorganized.—The Cincinnati Department of Health has reorganized under seven subdepartments, to be known as those of the board of health, health officers, medical inspection and relief, schools, infectious diseases, outdoor relief and tuberculosis At the head of each of the last five divisions will be an officer who will devote his entire time to the work

Elections.—The Cincinnati Society for Medical Research, at its annual meeting, December 1, elected the following officers president, Dr William Wherry, vice-president, Dr. Simon P. Kramer, secretary treasurer, Dr. Jacob L Tuechter, and executive committee, Drs Paul G Woolley and Irving Fisher.——At the annual election of the Cincinnati Polyclinic and Postgraduate School the following officers were elected: president, Dr Charles T. Souther; vice president, Dr. Adolf F. Morgenstern, secretary-treasurer, Dr Oscar W. Stark, and director of clinics, Dr. Albert E Hussey.

PENNSYLVANIA

Medical Club Election—At the annual meeting of the Oil City Medical Club, held December 1, the following officers were elected· president, Dr John L Hadley; vice president, Dr Winnie K Mount; secretary, Dr. Sylvester W. Sellew, and treasurer, Dr Frank B Jackson

Personal—Dr Edward Martin, the newly elected professor of surgery at the University of Pennsylvania, represented that institution at the annual banquet of the Colorado alumni at Denver on December 17 and at the banquet of the Pacific Southwest alumni at Los Angeles December 22——Dr. Thomas Veiel, of Stuttgart, Germany, and Dr William F. Blake, of San Francisco, have been visitors to Philadelphia during the present week

Annex for Tuberculosis Hospital.—The College Club of Pittsburg, on November 30, held a meeting in support of the project of establishing a tuberculosis annex of the Woman's Hospital for tuberculosis patients The proposed annex will provide five rooms for private patients, two of which are to be at the disposal of the College Club The cost of the new annex is estimated at $5,000 Donations and pledges amounting to $1 200 have already been received

Fine for Munyon.—December 16, the Munyon Homeopathic Home Remedy Company is said to have paid a fine of $600 imposed by Judge McPherson in the U S District Court, for misbranding certain "specifics" Special agent Jenkins of the government food and drug bureau, Dr Rudderman, of Nashville, Tenn, a government analytical chemist, and other government officials analyzed Munyon's Asthma Cure, Munyon's Blood Cure, the Munyon's Special Liquid Blood Cure, etc, the latter claiming to cure any number of blood affections Dr Edward M Gramm, a homeopath, testified that the remedies contained nothing that would effect a cure of the ills advertised on the labels

Philadelphia

Officers Elected.—The annual meeting of the Philadelphia Medical Examiners' Association was held and the following officers were elected president Dr A J Gaillard· vice president, Dr Francis S Ferris, secretary, Dr. Joseph D Farrar, and treasurer, Dr George D Morton——At a meeting of the West Philadelphia Medical Association, held December 5, the following officers were elected for 1911 president, Dr. Hiram L Lutz, vice president, Dr Charles P Pike, corresponding secretary, Dr Harry G. Hudson, financial secretary, Dr. William Miller, and treasurer, Dr Edmund L Graf——At the quarterly meeting of the Physicians' Motor Club of Philadelphia, on November 22, the following officers were elected· president, Dr Sigmund L Gans, vice presidents, Drs. L. Webster Fox, S Solis Cohen, and Edward E Montgomery; secretary, Dr. Sylvester J Deehan, and treasurer, Dr. James G Taylor.

SOUTH CAROLINA

Personal—Dr William J Burdell, Lugoff, has been made medical secretary of the Southern Division of the Esperanto Association of North America——Dr. Jesse F. Cleveland, Spartanburg, was seriously injured in a collision between a carriage and a passenger train, recently

Statue for Marion Sims.—The State Medical Society has started a movement to erect on the State House grounds, Columbia, a statue of Dr J Marion Sims. The proposed monument is to cost $10,000, of which the medical society will furnish $2,500, and the legislature will be asked to contribute $5,000

TENNESSEE

Personal.—Dr John B S Woolford, Chattanooga, has returned from abroad——Dr. Henry L Williford, Memphis, while being held up by a negro highwayman, November 23, killed the robber by cutting his throat——Rev. William Kelly, Nashville, for the past ten years a medical missionary in China, is visiting his home

Prevention of Blindness—The exhibit for the prevention of blindness *from the Russell* Sage Foundation has been shown in Memphis, Jackson, Humboldt, Nashville and Chattanooga. It was secured through Dr. Elizabeth C. Kane, Memphis, chairman of the Health Department of the Tennessee Federation of Women's Clubs.

TEXAS

Personal.—Dr. William M. Brumby, Austin, has resigned as state health officer and president of the State Board of Health to become medical director of the Equitable Life Insurance Company of Texas, San Antonio.——Dr. Ralph Steiner, Austin, has been offered the position of state health officer vacated by the resignation of Dr. William M. Brumby.——Dr. Charles P. Brewer, Fort Worth, narrowly escaped death in a fire which did about $8,000 damage to his property in Fort Worth recently.——Dr. C. C. Green has succeeded Dr. Frank R. Ross as assistant health officer of Houston.——Dr. E. E. Best, Cameron, has been appointed health officer of Milam county.——Dr. W. S. Winter, Jr., has been appointed assistant post surgeon of Port Arthur.

GENERAL NEWS

Examination for Anatomists.—The United States Civil Service Commission announces examinations Jan. 18, 1911, at various places throughout the United States to secure eligibles from which to make certification to fill a vacancy in the position of male anatomist at $1,600 per annum in the Army, medical museum, office of the surgeon general, and vacancies requiring similar qualifications as they may occur. Application should be made either to the United States Civil Service Commission, Washington, D. C., or to any local board of examiners.

Report of the Surgeon-General of the Navy.—The annual report of the Surgeon-General of the United States Navy, Chief of the Bureau of Medicine and Surgery, to the Secretary of the Navy for the fiscal year of 1910, shows a generally diminished damage ratio from disease, injuries, invalidings, and deaths as compared with the previous year and the average of the previous decade. The death rate of 5 per 1,000 is lower than has been previously recorded. The total admission ratio dropped from 725.36 to 698.25; the ratio of daily average of patients from 29.10 to 28.52; the average number of sick days for each individual from 10.56 to 10.41, and the ratio of total discharges from disability from 35.49 to 30.59. The total damage from disease alone in percentage of sick was 3.952, which is lower than for any year since 1898. These results are attributed to the increasingly recognized functions of the medical department to prevent the occurrence of disability rather than to await its inception to effect a cure. The establishment of a naval medical reserve corps is recommended to act as a recruiting body for the regular establishment. The prominent hygienic problems of the service are stated to be contagious and venereal diseases. The proportion of contagious diseases is lower than in former years but there exists what is considered a serious situation in regard to venereal disease, there having been more than 100 primary admissions for this class of affections during the first three months of the year, with an average complement of 1881 who have recently entered the service free from such disease. He advises consistent enforcement of venereal prophylaxis at training stations the same as on board ships. The surgeon-general disapproves of the physical test by riding, and suggests as a substitute the Swedish system of training. The admission rate for pulmonary tuberculosis has declined from 6.26 to 5.60.

MANILA LETTER

Manila, Nov. 5, 1910.

Pharmacy in the Philippines

Now that the Philippine Medical School is thoroughly established and is well under way in offering scientific instruction to its students, and the medical department of Santo Tomas University has shown signs of improvement, it has been thought well to take up the question of the Filipino pharmacist. The question of his efficiency and the local facilities for training pharmacists has been studied with a view of recommending necessary improvements in the existing courses in the three Manila schools of pharmacy, as well as looking toward the establishment of a school of pharmacy in connection with the Philippine Medical School and the University of the Philippines.

In the Philippines, pharmacy is considered one of the learned professions; the pharmacist is in rank next to the physician, and, like the latter, has too often proved ill trained for many of the simple duties of his trade. In many of the towns of the provinces he forms an important factor in the social scale and has sometimes engaged in politics.

In Manila there are good pharmacies, but with very few exceptions the provinces are without efficient or competent pharmacists. The training in the local schools of pharmacy is based on the Spanish system and is not in accord with the modern European methods. Thus we are facing the necessity of having the prescriptions of American and American-trained physicians sent to Manila to be filled. These prescriptions are sometimes written by Manila physicians, sent to the provinces and then returned to Manila to be filled. This state of affairs almost compels the graduates of the Philippine Medical School to be their own pharmacists in the provinces. Such a condition hampers the work of the bureau of health and will defeat many of the efforts of modern medical education in the Islands until improvement is brought about.

With the possible exception of one school—the school of pharmacy of Santo Tomas University—the institutions in Manila are in nowise prepared to train competent pharmacists. Even the graduates of the Santo Tomas school have great difficulty in passing the examinations of the board of pharmaceutical examiners, and radical changes must be made in this school to make it an efficient institution.

In July, 1909, twenty-three candidates entered the examinations of the board of pharmaceutical examiners. Only one passed. At the 1910 examination, twenty-six candidates were entered; not a single candidate passed. The highest grade given was 53 per cent.

The legal requirements are not to be considered drastic. They were made to suit the conditions of the country and are just as liberal as is compatible with public safety in the matter of fairly well-trained pharmacists. Any student who has had a moderately good training in pharmacy should have no trouble in passing the examinations.

If the educational facilities for training pharmacists are not soon improved it will probably be necessary to relax the legal requirements somewhat, otherwise the drug business will be monopolized by a small number of pharmacists. The Filipino is quick to take advantage and is decidedly mercenary when he controls the situation. For this reason it is not advisable to enforce rigidly the regulations covering the practice of midwifery in these islands. It was found in Manila that the few competent midwives would quickly run up their charges to exorbitant rates when the ban was put on their less capable sisters in the profession. The Filipino pharmacist, as well as the Filipino physician, usually regulates his charges by the necessity for his services in a particular case. In an emergency he is often a robber. As an example: one of the medical health officers had occasion to require immediately 2 liters of saline solution in an emergency case. He dispatched a messenger to the local *botica* (drug store) on a hurry-up call for the saline. The bill presented for the 2 liters was 16 pesos ($8.00).

LONDON LETTER

(From Our Regular Correspondent)

London, Dec. 3, 1910.

The Health of Children

The report for 1909 of the chief medical officer of the Board of Education, Dr. George Meredith, is a most important document. It covers the first complete year during which the children entering and leaving the public elementary schools of England and Wales have been subjected to systematic medical examination. It brings together a mass of new and authentic data on the physical condition of the rising generation and has an important bearing on the question of national degeneration, about which so much has been written and so little proved in recent years. The children attending the schools in all number 6,000,000. This comprised the whole of the children of the working class and a large part of the children of the middle class, the remaining children being sent to private schools. About 10 per cent. suffer from serious defects in vision, from 3 to 5 per cent. from defective hearing, 1 to 3 per cent. have suppurating ears, 8 per cent. have adenoids or enlarged tonsils of sufficient degree to obstruct the nose or throat and to require surgical treatment, 20 to 40 per cent. suffer from extensive decay of the teeth, 40 per cent have unclean heads, 1 per cent. suffer from ringworm, 1 per cent. from tuberculosis of a readily *recognizable* form, and 0.5 to 2 per cent. from heart disease. In cases in which disease is discovered measures are taken for its treatment. The fact is brought to the notice of the parents, the parents are assisted in the application of remedial measures and in case of persistent neglect are punished. Notwithstanding the prevalence and serious character of dental disease there is good hope of considerable success in dealing with it, for it seems to be largely due to total neglect of cleanliness of the mouth in childhood, and the necessity for such cleanliness is being more and more impressed on both children and parents by teachers, nurses and health officers. Dental clinics are being established, at which early conservative treatment is begun. The report marks an epoch in the history of education in this country and gives official recognition to the fact, long ignored, that before educating children their physical fitness must be insured.

New Theory as to the Spread of Sleeping-Sickness

Evidence is being brought forward that sleeping-sickness is spread by another fly than the *Glossina palpalis*. The latest fact on this point comes from northwestern Rrodesia, particularly from a valley in which a tributary of the Zambesi flows, where a number of cases of sleeping-sickness have occurred among both whites and natives. In this district no *Glossina palpalis* has been found, and the nearest point at which the fly lives is 400 miles distant. Up to the present all preventive measures taken by the various governments have been in regard to this fly, whose location has been clearly defined. An elaborate map of Africa has been prepared in which the various *Glossina palpalis* areas have been specially colored, and wherever possible, the belt infected by this creature has been cleared and the inhabitants removed to a healthy zone. But if this new theory be adopted future measures will have to be more extensive. The newly suspected fly is another species of tsetse fly, known as the *Glossina morsitans*, which is found in regions much further south than the *Glossina palpalis*, where the latter is unknown.

Florence Nightingale's Will

Miss Florence Nightingale's remarkable character is shown by the directions which she gave as to the disposal of her body. She willed her body to medical science for dissection and requested that, if possible, no memorial, or one of the simplest character, should mark the place of burial; also that the burial services should be extremely simple.

An Actuarial Study of the Influence of Sanatoriums on Pulmonary Tuberculosis

Two actuaries, Mr. W. P. Elderton and Mr. S. J. Perry, have made an important investigation, which even in the voluminous literature of tuberculosis is absolutely new. They have made an actuarial study of the influence of sanatoriums on the expectation of life of the subjects of tuberculosis. The material used was collected by Dr. Noel Bardswell in this country and by Drs. Lawrason Brown and Pope in America. The figures are analyzed and the expectation of life is compared with that given in the Registrar-General's English life-table. It is found that even in cases of tuberculosis in which the treatment has been most successful the expectation of life is much shortened. A comparison is also made between the results obtained before the introduction of the sanatorium treatment and those obtained since it has been adopted. Difficulties were found in making this comparison, but the surprising conclusion is reached that the figures show no superiority in the results of sanatorium treatment. The authors freely admit that their results require confirmation in the light of fuller statistics. Even so, their importance is obvious.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec. 2, 1910.

Prizes of the Academy of Sciences

The Académie des sciences has awarded three Montyon prizes in medicine and surgery, each of $500 (2,500 francs); one to Drs. G. Martin, Leboeuf and Roubaud for their work, "Report of the Commission on the Study of Sleeping-Sickness in the French Congo, 1906-08;" the second to Prof. J. Dejerine and Dr. André Thomas of Paris, for their work on diseases of the spinal cord; the third to Dr. E. Perroncito, professor in the Turin medical college, for his work on the diseases of the miners from the St. Gothard to the Simplon. Three prizes of $300 (1,500 francs) have been awarded: the first to Dr. C. Mantoux of Cannes, for his work on the intradermal reaction to tuberculin; the second to Dr. P. Emile Weil of Paris, for his work on hemophilia; the third to Dr. G. Moussu, professor of the veterinary school at Alfort and to M. Monvoisin, for their works on the milk of tuberculous cows. The Barbier prize, $400 (2,000 francs), has been divided between Dr. A. Thiroux, physician to the colonial troops and director of the bacteriologic laboratory of St. Louis, Senegal, for his work on sleeping-sickness and the animal trypanosomiases in Senegal, and M. H. Bierry of the laboratory of experimental physiology of the Sorbonne, for all of his works. The Bréant prize, $20,000 (100,000 francs), intended to reward the discoverer of a cure for Asiatic cholera, has of course not been awarded. Out of the interest of this sum, a prize of $700 (3,500 francs) has been awarded to Dr. Jules Bordet, director of the Pasteur Institute of Brabant, for his "Chemical Theories of Immunity" and "Study of the Serum of Vaccinated Animals, Toxins and Antitoxins," and a prize of $300 (1,500 francs) to Dr. A. Taurelli Salimbeni, head of the laboratory at the Pasteur Institute of Paris, for his work on cholera and the vibrios. The Godard prize, $200 (1,000 francs), has been awarded to Drs. L. Ambard and E. Papin of Paris, for their "Study of Urinary Concentrations." The Dusgate prize, $500 (2,500 francs), has been awarded to Dr. Séverin Icard of Marseilles, for his memoir entitled "Report of Deaths in Hospitals in France and Abroad; Utility of Early Necropsy and Necessity for an Early Diagnosis of Real Death, Permitting Early Necropsy." The Bellion prize, $280 (1,400 francs), has been shared between Dr. Imbeaux, chief engineer of bridges and roads at Nancy, for his "Statistical and Descriptive Annual Report of the Distribution of Water," and M. Frois, labor inspector, and M. Sartory, secretary of the Commission of Industrial Hygiene, for their memoir entitled: "Lyes and Organic Powders in Industry." The prize of Baron Larrey, $150 (750 francs), has been divided between Dr. Chavigny, *agrégé* professor at the school of military medicine at Val-de-Grâce, for his work on military psychiatry, and Dr. Miramond de La Roquette, military physician at Nancy, for his work on the scapular girdle. The Mège prize, $2,000 (10,000 francs), has not been awarded. A prize from the interest has been awarded to Mlle. J. Joteyko, of the laboratory of psychophysiology at the University of Brussels, and Mlle. Stefanowska, for their work on muscular function and the psychophysiology of pain.

In physiology the Montyon prize of experimental physiology, $150 (750 francs), has been divided between Prof. C. Livon of Marseilles, for his works on experimental physiology, and M. Marin Molliard, for his "Organic Nutrition of the Higher Vegetables." The Philipeaux prize, $180 (900 francs), has been awarded to Dr. Maurice Arthus, professor of physiology at the University of Lausanne, for his "Sero-Anaphylaxis of the Rabbit." The Lallemand prize, $360 (1,800 francs), has been divided between M. René Legendre, for his "Nerve Cellule of *Helix Pomatia*," and M. Aldo Perroncito, for his "Cellular Elements in the Process of Degeneration of the Nerves." The Martin-Damourette prize, $280 (1,400 francs), for a work on therapeutic physiology, has been awarded to Dr. E. Laguesse, professor of histology at the Lille medical school, for his work on the pancreas.

Juvenile Crime

In a report to the General Council of the Department of the Seine, M. Ambroise Rendu published suggestive statistics among minors. Out of every 1,000 crimes against persons, four are committed by minors under 16 years, and 164 by minors aged from 16 to 20. Out of every 1,000 crimes against property, two are committed by minors under 16, and 178 by minors aged from 16 to 20. In 1905, 3,805 boys and 566 girls under 16 were before the courts; in 1909, there were 4,517 boys and 703 girls. Believing that it is time to combat this proportion of crime among minors, M. Ambroise Rendu has invited the general council to pass the following resolutions: (1) that minors arrested for any offense should be transported in special conveyances without contact with other arrested persons; (2) that minors' cases should be tried before a special magistrate; (3) that such cases should be tried in *chambre de conseil*, that is, not publicly, but with the aid of a representative of a society for the protection of children.

Contamination of Oysters

While the oyster is believed to possess the power of selecting its food by repelling unsuitable material, the water which it respires penetrates quite freely, unfiltered, and with all its impurities. If this be true, the danger from infection from contaminated oysters would arise much less from the contents of the digestive tube than from the liquid which bathes the respiratory organs and remains in the shells until the oysters are eaten From a communication made in one of the last sessions of the Académie des sciences by M Fabre Domergue, it appears, however, that oysters are capable, in an impure medium, of ingesting a massive dose of detritus of stercoral origin, which may contain germs of infectious intestinal diseases More importance, then, should be attached to the bacteriologic analysis of the oysters themselves, their intestinal contents and their liquor—too much neglected up to the present in France—than to the water of the beds, the degree of infection of which varies, moreover, in large degree from one time to another.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec 1, 1910

Personal

Professor Erb celebrated his seventieth birthday November 30 This distinguished clinician, who still enjoys remarkable physical and mental activity, resigned his teaching position some years ago

Professor La Valette St George, professor of anatomy at Bonn died November 30 at the age of 79 He was a pupil of Kolliker and John Muller, joined the Bonn faculty in 1858, became regular professor in 1865 and head of the anatomic department in Bonn in 1875 His most important work was in the field of comparative anatomy, especially the history of evolution In 1907 he resigned his professorship

Professor Eberth, director of the pathologic institute at Halle, will resign his position at the end of the winter semester, on account of his advanced age

Privat docent Dr Heineke has been appointed director of the university surgical policlinic at Leipsic

Law Against Quackery and Nostrums

The principal feature of the proposed law, the bill for which, as I have mentioned, has been recently placed before the Reichstag by the government, is to compel the quacks to announce themselves to the authorities and to subject themselves to control by which they are required to keep business records in which a report is made of their business transactions The following are to be forbidden by the law any treatment that is not founded on personal investigation, such as treatment by mail, etc, treatment by mystic processes, especially faith healing, the treatment of diseases dangerous to the community, which are included under the imperial infectious diseases act, that is, cholera, plague, leprosy, typhus, smallpox and yellow fever, treatment of all diseases or injuries of the sexual organs, especially venereal diseases, the latter even when they affect other parts of the body, the treatment of cancer, treatment by hypnosis, the treatment by the use of narcotics which may extend beyond the part treated, and treatment by hypodermic or intravenous injection The imperial upper house (*Bundesrat*) can prohibit the treatment of other diseases Furthermore, quacks are not to be permitted to administer medicines themselves nor shall they refer their customers to special sources as to supply The trade of the quack is to be forbidden if the facts justify the assumption that by the pursuit of his trade the life of a human being or animal is endangered or health injured or that the customers are being swindled Further, their occupation can be forbidden if they are convicted of a punishable transaction in the course of their business or if their civil rights are forfeited in any other misdemeanor Against fraudulent secret remedies, it is provided that any one shall be punished with imprisonment up to one year and with a fine up to $250 (1 000 marks), who shall in public advertisements which concern the prevention, mitigation or cure of disease in man or animals or tonic remedies for man or animals or infant food, make statements which are not scientifically true and are calculated to deceive the public If the transaction is only negligent, the imprisonment shall be limited to only three months and the fine to $150 (600 marks) It may also be provided that the verdict shall be published at the cost of the convicted I will report on the other details when the law has been passed It is at least to be hoped that it will be passed, although in the discussion so far, objections against a number of the provisions have been raised by all of the speakers The bill is next to be submitted to a committee of the delegates for consideration

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Dec 1, 1910.

Warning Against Certain Scholarships for Medical Students

The scarcity of practitioners in the country has had unpleasant results, and several efforts have been made to induce good men to undertake country practice But as the people are not very rich and the appointments are not too well paid, the country magistrates have always had difficulty in obtaining adequate medical help The party now in power has besides made it a special point to appoint only doctors who fulfil certain national and religious requirements rather than those of scientific education The existence and development of a powerful medical organization, which soon began to pay special attention to the country appointments, still further embarrassed the ruling party by boycotting all appointments below a certain sum In order to counteract the effect of these and similar measures, a number of scholarships valued each at from 600 to 1,000 kronen ($120 to $200) a year, have been offered to medical students from their third university year, under the condition that these men will pledge themselves to enter the services of the country magistrates after having completed their study They would, of course, be sent where the low payment deters regular doctors from settling, and they would have to obey, being under a contract A warning has been issued by the medical organization, explaining matters to the medical students, and showing how such a contract, being agreed on for at least ten years, would mean actual sweating and ruin for the young doctor Hitherto the plan of scholarships has not been very successful

Centralization of Public Charity

For several months efforts have been made to bring about a complete change of the mode of administration of public charitable institutes, including hospitals in Lower Austria (Vienna Letter, The Journal, Feb 5, 1910, p 479). The pretext is the unsatisfactory financial condition of the phantom Vienna "hospital fund" which was long since exhausted in reality, but which preserves a fictitious existence and still keeps the hospitals running by means of loans The fund is in the hands of the government of Lower Austria and its yearly deficit amounts at present to some 1,500,000 kronen As the legal responsibility for the expenses of the hospitals is not fixed on the general government, the municipality or the diet, the latter has offered to take this matter into its own hands under the condition that besides a loan of 10 000,000 a tax of 5 per cent on all rates be granted for this purpose This appears not impossible, but the other conditions have quite a different bearing The diet intends to form a corporation of thirty two men, in which only two representatives of medical men will sit, the remainder being elected or appointed by the general government, the diet and the city of Vienna The latter two authorities belong to the well known reactionary and antimedical party at present in power The above mentioned managers are to be given the supreme control over all hospital directors both in Vienna and in the country, and even over the clinics The appointment of hospital directors as well as of members of the hospital staff is to be in their hands They will be bound nominally to elect a candidate out of three men nominated by the hospital staff, but this of course does not preclude other possibilities It is also intended to make the appointments of hospital doctors permanent, for life, the service to occupy a man's whole time, so that a large number of graduates from the university would be excluded from practical learning Such plans interfere seriously with the future of the medical profession in this country, as it is well known that nepotism and friendship have a great deal to do with this political party

As soon as the outlines of this plan became known in medical circles much indignation and opposition were aroused A protest meeting, in which all hospital directors as well as university professors were present or were represented took place a short time ago and an urgent appeal was directed to the government to call its attention to the danger threatening the population On the other hand, the proposed tax of 5 per cent on all taxes means a heavy addition to the heavy burden now weighing on the rate payers Large sums of money are involved, as the hospitals coming under the scope of the plan have over 16 000 beds The resistance offered by a large section of the population will perhaps be successful in warding off this attack

Pharmacology

"PROFESSOR" SAMUELS AND HIS EYE WATER

One of the latest comets to flash across the firmament of quackery is "Professor" H. Samuels, who hails from Wichita, Kansas. Samuels claims that he is "the only living person" who "treats through the eye" the following diseases:

Consumption
Fits
Cataracts
Paralysis
Blindness
Eczema
Bright's Disease
Morphin Habit
Heart Trouble

These are but a tithe of the numerous ailments that this new apostle of quackery offers to "cure." Samuels has been lavishly spending his easily made money in advertising space. One-third of a city daily's page is no unusual amount of space for him to use for a single advertisement.

The business is conducted along the lines of the typical mail-order fake. A series of "follow-up" circular letters so printed as to simulate individual type-written letters, "symptom blanks," the inevitable and ubiquitous testimonial—these and such other paraphernalia as go to make up the stock-in-trade of the quack, are used by Samuels in his process of swindling the sick and humbugging the helpless. He emphasizes two points in all his advertising claptrap. First he wishes to treat only "hard cases, cases that the regular doctor can do nothing for;" second, he wants it generally known that he has been arrested many times for irregular practice.

Samuels' "remedy" consists of an "eye water" which is claimed to have cured ovarian tumor, "paralysis of the optic nerve," deafness, tuberculosis and various other ills. Two specimens of the "eye water" alleged to be used by Samuels have been sent in by correspondents, from whom we learn that $25.00 an ounce is charged for the stuff. A cursory examination of both samples has been made in the Association laboratory and our chemists report as follows:

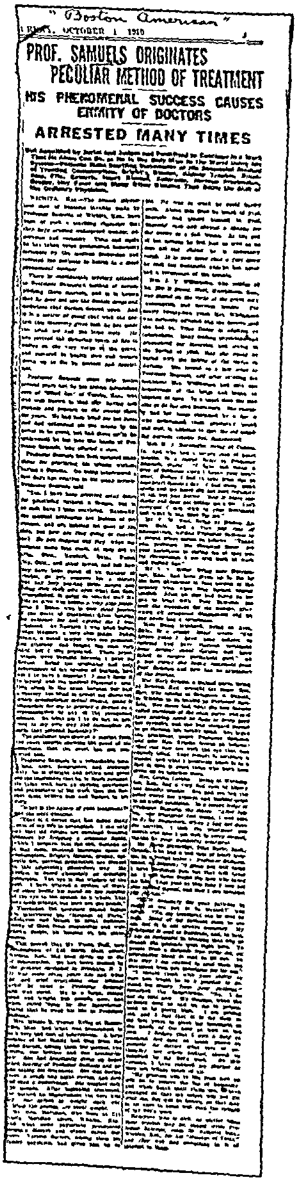
"Each of the two samples of the solution alleged to be used by Professor Samuels was a colorless, slightly turbid liquid having a salty taste. Each gave tests for sodium, chlorid, sugar and a trace of sulphate. In neither were metals such as arsenic, copper, lead, iron, etc., present and in neither could any potent alkaloids be detected.

"One of the samples examined was too small to make a quantitative test practicable. Examination of the larger sample showed that the sodium chlorid and sugar were each present in about the same quantity, viz., 7.5 grams in 100 c.c. (about 35 grains to the fluid ounce).

"The following formula gives a solution which is practically identical with the larger sample examined:

Table salt	10 ounces
Sugar	10 ounces
Hydrant water	1 gallon

"Approximate value 6 cents a gallon; alleged selling price $25.00 an ounce."



" Boston American "
OCTOBER 1 1910
PROF. SAMUELS ORIGINATES PECULIAR METHOD OF TREATMENT
HIS PHENOMENAL SUCCESS CAUSES ENMITY OF DOCTORS
ARRESTED MANY TIMES

Photographic reproduction (greatly reduced) of a two-column advertisement of "Professor" Samuels.—From the *Boston American.*

The absurdity of attempting to cure consumption, the morphin habit, ovarian tumor and scores of other pathologic conditions, by merely dropping a weak solution of salt and sugar in the eye, would seem sufficiently apparent to render quackery of that sort unprofitable. So it would be, were it not for the credulity and unfailing optimism of the chronically ill toward all new "treatments." Samuels' reasons for wanting to "treat" chronic diseases are evident. The quack who attempted to relieve a man's toothache or headache by dropping a little salt water in his eye and charging $25.00 for the process, would find few victims. But with sufferers from chronic diseases the case is different. Ninety-nine consumptives out of a hundred will, for the first few weeks, agree that they have been benefited after having experimented with some new "treatment." And the less scientific the treatment and the more wildly improbable the claims made for it, the greater will be the alleged benefit derived from it.

To devote more space to this humbug would be to dignify it. Suffice it to say the whole business is founded on falsehood and fraud. Any man who will take money from a consumptive, an epileptic or a morphin habitué under pretense of curing his disease with such an inert mixture as that just described is an unconscionable scoundrel.

It is a sorry commentary on our civilization that the incurably ill cannot, apparently, be protected against their own credulity and the wiles of those who would fatten on their misfortune and profit by their sufferings.

[Contribution from the Chemical Laboratory of the American Medical Association]

MAGNESIUM PEROXID

W. A. Puckner and W. S. Hilpert

A number of peroxids such as zinc peroxid, magnesium peroxid and sodium peroxid have been offered to the profession as substitutes for the hydrogen peroxid solution of the Pharmacopeia and have received considerable attention of late. They are claimed to possess the oxygen-producing properties of the Aqua Hydrogenii Dioxidi, modified by the relative stability of the compounds and the metallic salts which are produced in their decomposition. The commercial products are usually mixtures containing but a limited amount of real peroxid; for example, commercial "magnesium peroxid" contains but about 15 per cent. of magnesium peroxid while commercial "sodium peroxid" contains about 75 per cent. of sodium peroxid.

The different peroxids vary considerably in their stability, their solubility and their ease of decomposition in solution. In solutions of acids the peroxids are decomposed, forming hydrogen peroxid and the salt of the metallic radicle of the peroxid. In this way the entire active oxygen-content of the peroxid is quickly made available in the form of hydrogen peroxid in solution. Water dissolves only minute quantities of these peroxids but it does decompose them with varying degrees of readiness. Thus zinc peroxid, although very insoluble, is decomposed by water into zinc hydroxid and hydrogen peroxid as follows:

$$\text{Zno}_2+2H_2O\text{—>}Zn(OH)_2+H_2O_2$$

ALKALINITY FAVORS DECOMPOSITION

It is well known that hydrogen peroxid is supposed to decompose with the formation of water and oxygen (H_2O_2—>H_2O+O). The decomposition of hydrogen peroxid in this manner is retarded, or takes place only to a slight extent, in the presence of acid, as is illustrated by the use of acids to preserve the commercial hydrogen peroxid solutions. On the other hand alkali favors the decomposition of hydrogen peroxid to water and oxygen and the rapidity with which hydrogen peroxid is decomposed is in direct proportion to the amount or strength of the alkali.

When sodium peroxid is decomposed by water a very strong alkali, sodium hydroxid (caustic soda), is formed and therefore the ready decomposition of the hydrogen peroxid is favored and hence the sodium peroxid has strong oxidizing powers. Magnesium peroxid in contact with water also forms an alkaline body, magnesium hydroxid, but which is a much weaker alkali than sodium hydroxid and correspondingly less active in decomposing the hydrogen peroxid present; for this reason magnesium peroxid is not so powerful an oxidizing agent as sodium peroxid. Zinc peroxid forms the weakest alkaline solution of all and is the least powerful oxidizer of the peroxids under consideration.

From this it appears that the energy of the oxidizing powers of different peroxids varies in direct ratio to the alkalinity of the solution produced in their decomposition. The variation in the alkalinity of the solutions formed, affects the therapeutic uses of the peroxid. Sodium peroxid is not desirable for therapeutic use because of the formation of the strongly alkaline solution of sodium hydroxid (caustic soda). Magnesium and zinc peroxids, on the other hand, yield weakly alkaline solutions and are for that reason more desirable.

ADVANTAGES CLAIMED

The advantages claimed for the peroxids of sodium, magnesium and zinc are that they can be used for the extemporaneous preparation of an oxidizing solution and that zinc and magnesium peroxids in contact with the moist surface of a wound or mucous membrane slowly liberate oxygen, *in situ*, at the point where it is most needed.

The claims regarding the value of these peroxids made by the manufacturers of these products, however, are not confined to such statements as the above, but are much more extravagant, wonderful properties being ascribed to the preparations.

A firm, which specializes in the manufacture of peroxids and which has advocated their promiscuous introduction in toilet preparations for the cleansing, bleaching and beautifying of the feet, teeth, face, hands, and nails and for the "rejuvenation of the skin," has made the following statements in advertising pamphlets:

> "Biologically, magnesium peroxid may be found to be a useful factor in cell formation, inasmuch as oxygen is essential for the growth of the protoplasm."

It has also been stated that it is " . . . a preventative of typhoid fever." Zinc peroxid has been claimed to be a "preventative of tetanus" and also "a skin food."

MAGNESIUM PEROXID AS FOUND ON THE MARKET

Magnesium peroxid is one of the preparations which was recommended for inclusion with the next pharmacopeia, by the Section on Stomatology of the American Medical Association, at the Sixtieth Annual Session, at Atlantic City, June 1909, and it is for this reason, of special interest to physicians. To determine the composition and state of purity of the available brands of commercial magnesium peroxid, their chemical examination was taken up by us in the Association laboratory.

The results of a preliminary examination of specimens of magnesium peroxid were submitted together with a tentative description to the firms whose labels appeared on the specimens. In view of the results found and of the criticism with which the descriptions met it was considered advisable to take up again the examination of magnesium peroxid, with the special object of determining the keeping quality of the product. Accordingly fresh specimens were purchased and also solicited directly from the firms marketing the product. In response to the request the Mallinckrodt Chemical Works, Powers, Weightman, Rosengarten Co., and the Roessler and Hasslacher Chemical Co. sent specimens, for which appreciation is at this time expressed. Specimens bearing the labels of these firms were purchased at the same time on the open market and were examined with the submitted specimens. At the same time samples of each of the six specimens were placed in small vials which were completely filled and tightly stoppered, and samples of the specimens purchased on the open market were placed in wide-mouth bottles with loosely-fitting stoppers and all set aside for six months, at the end of which time they were all again examined.

RESULTS OF EXAMINATION

Physically, the six specimens were practically identical, each being a light, white, tasteless and odorless powder, practically insoluble in water. Each sample was soluble in dilute acids, yielding a solution which responded to tests for peroxid, magnesium, chlorids and small quantities of sulphates, iron and calcium. The specimens also responded to tests for carbonate. In no case were heavy metals, such as lead, copper, arsenic, etc., found.

As the value of magnesium peroxid depends chiefly on its peroxid content, assays were made to determine the total available oxygen in each specimen and the results calculated to magnesium peroxid. The following table contains the magnesium peroxid content calculated from the available oxygen found both at the time the specimens were received and again six months later:

Brand[1]	Source	MgO_2 content as received	MgO_2 content 6 months later[2] *A*	*B*
R. & H.	Market	14.66	14.44	14.33
	R. & H.	25.18	18.26	.....
Mall.	Market	17.43	17.15	16.90
	Mall.	15.56	15.28	.....
P. W. R.	Market	12.17	11.20	11.50
	P. W. R.	15.45	14.63	.....

[1] "R. & H." refers to the Roessler and Hasslacher Chemical Co., "Mall." refers to Mallinckrodt Chemical Works and "P. W. R." refers to Powers, Weightman, Rosengarten Co.

[2] *A*—Specimens kept in vials completely filled and tightly stoppered. *B*—Specimens kept in vials partially filled and loosely stoppered.

These results show that the obtainable specimens of magnesium peroxid vary widely in their peroxid content and that the specimen containing a large amount of peroxid deteriorated rapidly on keeping; and that magnesium peroxid keeps equally well whether stored in completely filled, well stoppered bottles or in partially-filled, loosely-stoppered bottles.

THE CHLORID CONTENT

In making the qualitative test for chloride it was found that some specimens contained relatively large quantities of this impurity and accordingly the chlorid content was quantitatively determined with the following results:

Brand	Source	Chlorid (Cl) Per cent.
R. & H.	Market	6.89
	R. & H.	0.21
Mall.	Market	1.65
	Mall.	0.16
P. W. R.	Market	Trace
	P. W. R.	2.56

The results of this examination show that while the chlorid content varies rather widely, one specimen is practically free from this impurity. It is also interesting to note that, with the exception of one brand, the specimens sent by the firms contained less chlorid than the specimens purchased on the market.

WHAT THE RESULTS SHOW

The results as a whole show that the commercial magnesium peroxids vary considerably both as to composition and stability and they also show that magnesium peroxid of an acceptable state of purity and stability can be manufactured. The above examination demonstrates the need of a standard for magnesium peroxid and accordingly a tentative minimal standard of 15 per cent. real magnesium peroxid (MgO_2) with limits for permissible amounts of impurities was submitted to the three firms whose products were examined. In reply the Mallinckrodt Chemical Works pointed out "that magnesium peroxid deteriorates quite rapidly after manufacture until it reaches about 15 per cent., at which point it remains constant and stable," a condition practically found. Regarding the same point the Roessler and Hasslacher Chemical Co. wrote: "The amount of 15 per cent. magnesium peroxid is rather low to stamp it as standard," yet a specimen bearing the label of this firm, purchased on the market, was found to contain somewhat less than this amount.

A SUGGESTED STANDARD

Considering the available data together with the results of this examination it is recommended that magnesium peroxid be required to comply with the following provisional description:

Physical Characteristics.—Magnesium peroxid is a white, tasteless, odorless and amorphous powder, practically insoluble in water, but soluble in dilute acids.

Chemical Characteristics.—If about 1 gm. magnesium peroxid be dissolved in 25 c.c. dilute nitric acid and 2 c.c. tenth-normal silver nitrate added to the solution and the resulting precipitate filtered off, the further addition of a few drops of silver nitrate solution to the filtrate should not produce a turbidity (limit of chlorids).

If about 1 gm. magnesium peroxid be exposed to the full heat of a Bunsen flame for five minutes, then dissolved in 25 c.c. dilute hydrochloric acid and the solution made up to 100 c.c., a solution will result which will conform to the following tests:

Ten c.c. of the solution saturated with hydrogen sulphid should yield no precipitate, nor become colored (limit of heavy metals).

Ten c.c. of the solution to which 10 c.c. ammonium chlorid solution and ammonium hydroxid in excess have been added, should yield not more than a turbidity on the addition of ammonium carbonate (limit of calcium).

Ten c.c. of the solution should yield not more than a turbidity on the addition of barium chlorid solution (limit of sulphates).

Ten c.c. of the solution should not immediately give a blue color on the addition of a drop of potassium ferrocyanid solution (limit of iron).

If 0.2 to 0.3 gm. magnesium peroxid, weighed into a flask, be dissolved with 20 c.c. dilute sulphuric acid, the solution diluted with 50 c.c. water, the titration of this solution with tenth-normal potassium permanganate should indicate the presence of not less than 15 per cent. magnesium peroxid, MgO_2. (1 c.c. tenth-normal potassium permanganate is equivalent to 0.00279 gm. MgO_2.)

Marriages

Sidney H. Streett, M.D., Baltimore, to Miss Mae Green, at Baltimore, November 23.

Frank L. Sutton, M.D., to Miss Mary Russell, both of Sedalia, Mo., December 1.

James Fitzgibbon, M.D., to Miss Alice Barbian, both of Racine, Wis., November 24.

Halsey Beach Loder, M.D., Boston, to Miss Beatrice Byers, at Indianapolis, December 17.

Bjarne Ravn, M.D., Scandinavia, Wis., to Miss Myrtle Frogner, of Iola, Wis., December 1.

Howell Shoener Zulick, M.D., to Miss Marguerite Patton, both of Philadelphia, December 7.

Claude Watson, M.D., Nebraska City, Neb., to Mrs. Sarah Wodehouse of Lincoln, December 7.

Charles J. Overman, M.D., Marion, Ind., to Miss Anna Mary Johnson of Urbana, O., December 14.

William Barnett Owen, M.D., Louisville, to Miss Emily Vance of Lexington, Ky., December 8.

Moses Lane Strathern, M.D., Faribault, Minn., to Miss Anna Ellis of Ishpeming, Mich., recently.

Joseph Louis Ransohoff, M.D., Cincinnati, to Miss Doris Kaufman of Paris, France, December 11.

Arthur Clyde Thorpe, M.D., to Miss Florence Chase, both of Los Angeles, at Lankershim, Cal., November 30.

William Campbell Posey, M.D., Philadelphia, to Miss Haddassah Hamilton Felton of Chicago, December 14.

Ira Carleton Chase, M.D., Fort Worth, Tex., to Miss Helene Irene Keatinge of New York City, December 15.

David B. Knox, M.D., Georgetown, Ky., to Miss Susan Parrish Phelps, of Richmond, Ky., at Lexington, December 8.

Deaths

Henry Hutchinson, M.D. Hahnemann Medical College, Philadelphia, 1874; of St. Paul; a member of the State Board of Health since 1894, and for the last nine years its president; a member of the staff of the St. Paul City and County Hospital. St. Luke and St. Joseph's hospitals; a member of the American Public Health Association and Minnesota State Sanitary Association; professor of theory and practice of medicine in the College of Homeopathic Medicine and Surgery of the University of Minnesota; died suddenly in a hotel in Mustapha Superior, Algiers, North Africa, December 1, from heart disease, aged 61.

Alpheus Albert Deering, M.D. Medical School of Maine, Brunswick, 1868; a member of the American Medical Association; once secretary of the Iowa State Medical Society, and for twenty years secretary of the Central District Medical Association; district surgeon of the Chicago and Northwestern Railway Company at Boone, Iowa; formerly postmaster of Boone, a director of the Ericson Library and the Eleanor Moore Hospital; died in the latter institution, December 3, after an operation for disease of the kidneys, aged 65.

Clarke Gapen, M.D. Northwestern University Medical School, Chicago, 1875; a member of the American Medical Association; formerly professor of medical jurisprudence in the Wisconsin State University and College of Physicians and Surgeons, Chicago; for three years superintendent of the Kankakee State Hospital; formerly commissioner of health of Omaha; died at his home in Madison, Wis., December 17, from disease of the heart and kidneys, aged 60.

Ole Tollefson Hoftoe, M.D. Rush Medical College, 1885; a member of the American Medical Association; for several years local surgeon of the Chicago, Milwaukee and St. Paul Railway Company, at Lanesboro, Minn.; and afterward a practitioner of Abercrombie, N. Dak., for ten years, and for three years coroner of Richland county; died at his home in New London, Minn., November 13, from carcinoma of the stomach, aged 56.

Thomas M. Chaney, M.D. University of Maryland, Baltimore, 1866; a member of the American Medical Association; acting assistant surgeon in the Army from 1866 to 1867; until five years ago a practitioner of Baltimore; and since then a resident of Chaney; president of the Calvert County Medical Society; died at his home, December 6, from neurasthenia, aged 69.

George E. Goodfellow, M.D. University of Wooster, Cleveland, 1876; of Tucson, Ariz.; a member of the American Medical Association; for five years chief surgeon of the Southern Pacific Railroad lines in Mexico; a surgeon in the Spanish-American War with service in Cuba; died in the Angelus Hospital, Los Angeles, December 7, aged 54.

Thomas Robinson Little, M.D. University of Pennsylvania, Philadelphia, 1900; a member of the American Medical Association; medical director of the Southern Life and Trust Company; died at his home in Greensboro, N. C., in November, from edema of the lungs, consequent on asthma, from which he had suffered for several years, aged 36.

Thomas Coit Fanning, M.D. New York University, New York City, 1861; formerly assistant at the Walters Park (Pa.) Sanitarium; for two terms a member of the board of trustees of Tarrytown, N. Y., and afterward water commissioner; died at Stamford Hall, Stamford, Conn., November 4, from cerebral hemorrhage, aged 70.

E. Lawrence Herriott, M.D. University of Nashville, Tenn., 1860; a member of the American Medical Association; acting assistant surgeon, U. S. Army, during the Civil War; until three years ago a practitioner of Jacksonville, Ill., when he moved to San Antonio, Tex.; died at his home in that city, November 30, aged 77.

Michael F. Gallagher, M.D. Georgetown University, Washington, D. C., 1889; Bertillon identification expert in the Department of Commerce and Labor, Washington; and a member of the Microscopical Society of the District of Columbia; died at his home in Washington, November 25, from angina pectoris, aged 52.

Horace Babcock, M.D. University of Buffalo, 1851; a practitioner of Wisconsin until 1862, when he entered the United States service as surgeon of the Second Wisconsin Volunteer Infantry; after the Civil War, a resident and practitioner of Gowanda, N. Y.; died at his home in that place, December 3, aged 86.

Walter Henry Wentworth, M.D. College of Physicians and Surgeons, New York City, 1863; acting assistant surgeon, U.

S. Navy during the Civil War; and for many years a practitioner of Pittsfield, Mass.; died suddenly at his home in Providence, R. I., December 7, from cerebral hemorrhage, aged 69.

Asa King Warren, M.D. University of Michigan, Ann Arbor, 1856; for 30 years a member of the board of trustees of Olivet (Mich.) College; for two terms state representative and for one term senator; treasurer of Eaton county; died at his home in Charlotte, December 9, from nephritis, aged 80.

Charles O. Chester, M.D. University of Buffalo, N. Y., 1876; of Buffalo; a member of the Medical Society of the County of Erie; formerly surgeon of the Charity Eye and Ear Dispensary; a specialist on diseases of the nose and throat; died in the Buffalo State Hospital, November 22, from paresis, aged 54.

Benjamin Coffin Taber, a practitioner of Illinois for twenty-five years; then a resident of California, and for the last twenty years a practitioner of Texas, and a member of the State Board of Health; died at the home of his daughter in Dennison, November 12, from senile debility, aged 97.

Frederick William Kirkham, M.D. University of Cambridge, England, 1882; L.R.C.S., Edinburgh, 1882; L.R.C.P., Edinburgh, 1889; a member of the State Medical Association of Texas; county physician of Cameron county; died at his home in Brownsville, September 19, from uremia, aged 51.

Francis Marion Charles, M.D. Howard University, Washington, D. C., 1894; a veteran of the Civil War; and since 1891 a clerk in the office of the Civil Service Commissioner, Washington, D. C.; died at his home in Washington, November 29, from cerebral hemorrhage, aged 66.

James Edgar White, M.D. Rush Medical College, 1883; one of the organizers and supreme medical director of the Court of Honor; until 1906 a practitioner of Urbana, Ill.; died at his home in Springfield, Ill., December 10, from cerebral hemorrhage, aged 55.

Robert E. VanNaten, M.D. Eclectic Medical College of Philadelphia, 1863; a veteran of the Civil War; postmaster of Cooperstown, Pa., for sixteen years and a school director for twenty-six years; died at his home, December 4, from angina pectoris, aged 70.

Oliver J. Thibodo, M.D. Queen's University, Kingston, Ont., 1857; a pioneer practitioner of Phoenix, Ariz; for many years a surgeon on transatlantic steamers; died at the home of his daughter in Los Angeles, November 26, from cerebral hemorrhage, aged 76.

Frederick B. McNeal, M.D. Bellevue Hospital Medical College, 1867; a veteran of the Civil War; elected state dairy and food commissioner of Ohio in 1891 and reelected in 1893; died at his home in Troy, November 30, from pneumonia, aged 70.

Henry Hammond Gallison, M.D. Harvard Medical School, 1872; a member of the American Medical Association; and an artist of considerable distinction; died at his home in Cambridge, Mass., October 12, from cerebral hemorrhage, aged 60.

John A. Swope, M.D. Pennsylvania Medical College, Gettysburg, about 1850; representative from Pennsylvania in the forty-eighth and forty-ninth congresses, and later a resident of Washington; died at his home in that city, December 6, aged 82.

Crawford E. Phillips, M.D. Bennett Medical College, Chicago, 1886; a member of the American Medical Association; formerly of Wilton, Wis.; died September 17, at the home of his son in Scott's Mills, Ore., from pneumonia, aged 57.

Simon Peter Burkhart, M.D. Philadelphia University of Medicine and Surgery, 1872; a practitioner of Blair, Center, and Clearfield counties, Pa.; died at the home of his daughter in Altoona, November 22, from senile debility, aged 75.

Amos Button Heard, M.D. Detroit Medical College, 1872; a veteran of the Civil War; for several terms a member of the borough health board of Northeast, Pa.; died at his home, November 17, from valvular heart disease, aged 75.

William C. Van Buskirk, M.D. New York University, New York City, 1854; M. C. P. and S., Ont., 1877; first mayor and for thirty-five years medical health officer of St. Thomas, Ont.; died at his home, November 10, aged 86.

Benjamin Franklin Spurgeon, M.D. University of Louisville, Ky., 1874; a member of the Medical Society of the State of California; died at his home in Chico, November 23, from disease of the kidney and bladder, aged 57.

Joseph C. Rauth, M.D. Detroit College of Medicine, 1903; a member of the Ohio State Medical Association; coroner of Wyandot County; died at his home in Upper Sandusky, December 8, from typhoid fever, agegd 35.

Rudolf S. Dubs, M.D. University of Berlin, Germany, 1893; a member of the American Medical Association; physician to the Bethesda Home; died at his home in Chicago, December 18, from pleuropneumonia, aged 44.

Richard L. Cook, M.D. Medical School of Maine, Brunswick, 1860; of Sturgeon Bay, Wis.; a surgeon of volunteers during the Civil War; died suddenly in the Union Hotel, Sturgeon Bay, December 9, aged 77.

Horace Fabian Kilgore (license, Minn., 1883, exemption certificate); for more than thirty years a practitioner of Luverne, Minn.; died in Lemon City, Fla., September 6, from hemorrhage of the bowels, aged 76.

Ruffin Coleman, M.D. University of Nashville, Tenn., 1869; of Bouvoir, Miss.; a Confederate veteran; died in the Soldiers' Home, Mountain Creek, Ala., Sept. 24, 1909, from disease of the intestine, aged 64.

Bruce Wallace, M.D. Memphis (Tenn.) Hospital Medical College, 1882; a member of the State Medical Association of Texas; died at his home in Houston, July 31, from heart disease, aged 52.

William Francis Hussey, M.D. Tufts Medical School, Boston, 1905; a member of the Massachusetts Medical Society; died at his home in Roslindale, Boston, December 2, from heart disease, aged 29.

David Foss, M.D. Berkshire Medical College, Pittsfield, Mass., 1861; of Newburyport, Mass.; died in the Homeopathic Hospital, in that city, December 2, after a surgical operation, aged 73.

Everett Grover Cleveland Snider, M.D. University of Louisville, 1910; an intern in St. Vincent's Infirmary, Little Rock, Ark.; died in that institution, October 17, from typhoid fever, aged 26.

Frederick Ghostley, M.D. Minneapolis College of Physicians and Surgeons, 1909; who recently assumed charge of a hospital at International Falls; died at Anoka, Minn., May 3, aged 26.

John S. Watson, M.D. Bennett Medical College, Chicago, 1875; for many years a practitioner of Minooka, Ill.; died at his drug store in that place, December 9, from myocarditis, aged 65.

Job Byron Marcus Dickens, M.D. Eclectic Medical College of the City of New York, 1871; died at his home in Newburyport, Mass., December 3, from cerebral hemorrhage, aged 65.

John S. Shrawder, M.D. Jefferson Medical College, 1865; one of the earliest inventors of motor vehicles; died at his home in Collegeville, Pa., December 4, from acute gastritis, aged 71.

John Hugh Walsh, M.D. Medico-Chirurgical College of Philadelphia, 1908; died at his home in Philadelphia, November 28, from tuberculosis of the lungs, aged 34.

A. Procter Sherwin, M.D. New York Homeopathic Medical College, New York City, 1885; died at his home in Suffield, Conn., November 22, from pneumonia, aged 50.

James A. Cullop, M.D. Kentucky School of Medicine, Louisville, 1893; died at his home in Haskell, November 20, from pneumonia.

Correspondence

Prevention of Perforation in Submucous Resection of the Nasal Septum

To the Editor:—Concerning my article, published November 19, Dr. Albert Bardes suggests (The Journal, November 26, p. 1910) that we "incise the mucous membrane and perichondrium at B instead of at A and retract. Then dissect forward the tissue anterior to the incision and incise the cartilage at A. This allows the flap B to A to cover the stump of cartilage."

It apparently has not occurred to Dr. Bardes that, if his directions are followed exactly, there will be no stump of cartilage to be covered by the flap B to A. In my article I stated that "this projecting ledge of cartilage was found not only to be completely covered over, but also to appear to aid very materially in holding the edges of the wound in close apposition, acting somewhat as a natural splint." Several months ago I did a submucous resection in practically the manner described by Dr. Bardes. This one trial showed me that I was immeasurably increasing the difficulty of the operation, and at the same time doing away with the projecting ledge of cartilage, which I had found of such value. Dr. Bardes concludes his remarks with this sentence: "If this is not done the incised membrane undergoes cicatricial-retraction and leaves a dry and crusted surface, besides delaying healing." On the contrary, in my cases, more rapid healing and less crusting has been obtained by the method described than by any previous method used.

I must add, however, that my best results have been in three cases in which I have operated within the last few days, in each of which fine silk sutures approximated the edges of the wound.

Richard M. Nelson, M.D.,
Colon Hospital, Cristobal, C. Z.

Uniform Size and Card Index for Reprints and Advertisers

To the Editor:—I wish to suggest that The Journal use its influence to get some uniformity in the size of folio to be used in reprints of various sorts whether put out by authors or (other?) advertisers. If an index card of uniform size were adopted at the same time by advertisers and publishers and sent out with their articles a great deal that goes into the doctor's waste-paper basket would be preserved, indexed and used. I am by no means the originator of this idea but think it worth being called to the attention of the A. M. A. again. F. W. Starr, Stanley, Wis.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SODIUM CITRATE IN FURUNCULOSIS

To the Editor:—In reply to a communication in this department (Nov. 26, 1910, p. 1911) permit me to inform your correspondent that the formula for sodium citrate, as used in furunculosis in the inoculation department of St. Mary's Hospital, London, where Sir Almroth E. Wright is director and where I was formerly an assistant, is:

Sodii citratis	gr. 2
Sodii chloridi	gr. 20
Aquæ	℥ 1

Misce. Sig.: Apply externally as directed.

The preferable method of applying this solution is to cut a hole in a piece of oiled silk, or waxed paper, which is just large enough to allow the opening of the furuncle to stick through. Place over this hole a piece of cotton soaked in the solution and cover it with another piece of waxed paper and keep the dressing in place with strips of adhesive. When irritation becomes objectionable leave off for a few hours and resume when it subsides.

F. J. Clemenger, Asheville, N. C.

COMPATIBILITIES OF SILVER NITRATE, ALKALIES AND ALKALOIDS

To the Editor:—1. Kindly tell me what excipient I should use in silver nitrate pills. How is it that the silver does not act on the hyoscyamus that is so often prescribed with it?

2. We are told that alkalies and alkaloids should not be combined in a single prescription. If this is the case, should codein be prescribed with potassium iodid or ammonium chlorid? F. A. N.

Answer.—1. Silver nitrate should be prescribed in pill form with an inert vegetable powder, such as powdered licorice, with a little gum tragacanth as excipient. These pills should be freshly made. They have the advantage of being readily soluble, but, as silver nitrate acts on organic matter, they are liable to change in time. To obviate this it has been proposed to use wax or paraffin, which produces a mass that does not readily undergo chemical change, but is likely to be only slowly active on account of the insolubility of the excipient. The use of an inorganic powder, such as potassium nitrate or pure precipitated silicic acid, has been suggested. It is probable that kaolin would answer for this purpose and might be made adhesive by a small amount of tragacanth paste. It is probable that silver nitrate acts to some extent on hyoscyamus, if in solution, but if in the dry form, as in pills, there may be little or no change. In the stomach the silver nitrate probably would combine with the organic matter of the stomach secretion rather than with hyoscyamus.

2. Alkalies are incompatible with the salts of alkaloids because they precipitate the alkaloid from solution. The salts of the alkali metals are usually not alkaline, and do not precipitate the alkaloids as a rule. As an exception, we may note that iodids do precipitate solutions of the salts of some alkaloids. Potassium iodid is not an alkali, but a neutral salt. It will not precipitate solutions of codein, but it is usually safest to prescribe potassium iodid by itself. Ammonium chlorid is a neutral salt and does not precipitate alkaloids. It can, therefore, be used with solutions of salts of codein or with those of other alkaloids without danger of precipitation of the alkaloid.

The Public Service

Medical Department, U. S. Army

Changes for the week ended Dec. 17, 1910.

Mason, George L., D.S., December 2, reported for temporary duty at Fort William H. Harrison, Mont.

Bartlett, C. J., capt., December 9, granted leave of absence for one month and fifteen days.

Huntington, P. W., capt., December 9, orders relieving him from duty in the Philippine Islands revoked.

Fife, James D., capt., December 9, on arrival at San Francisco will proceed to Fort Slocum, N. Y., for duty.

Cutliffe, William O., M.R.C., December 13, reports departure from treatment at Walter Reed General Hospital, Takoma Park, D. C., on three months' leave of absence on surgeon's certificate of disability.

Wing, Franklin F., D.S., December 7, ordered to proceed from Fort D. A. Russell, Wyo., to Fort Crook, Neb.; thence to Fort Omaha, Neb.; thence to Fort Des Moines, Iowa, for temporary duty.

McCord, Donald P., M.R.C., December 10, relieved from duty at Fort Ward, Wash., and ordered to Fort George Wright, Wash., for duty.

Demmer, Charles C., lieut., December 10, relieved from duty at Fort Thomas, Ky., and ordered to Schofield Barracks, H. I., for duty on transport sailing from San Francisco March 5, 1911.

The following named officers of the Medical Corps are detailed to take the course of instruction at the Army Field Service School for Medical Officers, Fort Leavenworth, Kan., beginning about April 1, 1911: Reynolds, Frederick P., major; Fauntleroy, Powell C., major; Clayton, Jere B., major; Bispham, William N., major; Bevans, James L., captain; Thompson, Henry D., captain.

Ramsey, William H., C.S., December 8, left Omaha on thirty days' leave of absence.

Craig, Charles F., capt., December 12, detailed to represent the Army at the meeting of the American Association for the Advancement of Science, to be held at Minneapolis, Minn., Dec. 27 to 30, 1910.

Kelly, John P., M.R.C., December 12, on arrival at San Francisco will proceed to his home. Lieutenant Kelly is relieved from active duty in the Medical Reserve Corps, to take effect on the expiration of his leave of absence.

Edwards, George M., lieut., December 13, will make one visit per week for a period not to exceed two months, beginning Dec. 19, 1910, to New York City, for the purpose of making a special study of eye refraction.

Heflebower, R. C., lieut., December 14, relieved from duty at Fort Hamilton, N. Y., and ordered to Army General Hospital, Fort Bayard, N. Mex., for duty.

Long, Charles J., D.S., December 9, reported for duty at Fort Andrews, Mass.

Birmingham, H. P., lieut.-col., and Kean, Jefferson R., lieut.-col., December 14, detailed members of an Army retiring board to meet at Washington, D. C.

Brown, Henry L., capt., December 8, left Fort Morgan, Ala., on fifteen days' leave of absence.

Talbot, E. M., capt., December 13, left Fort D. A. Russell, Wyo., on eighteen days' leave of absence.

Weed, Mark D., lieut., December 16, left Walter Reed General Hospital, Takoma Park, D. C., on ten days' leave of absence.

Medical Corps, U. S. Navy

Changes for the week ended Dec. 17, 1910.

White, E. C., P. A. surgeon, detached from the naval hospital, Mare Island, Cal., and ordered to the *Vicksburg*.

Biello, J. A., asst.-surgeon, detached from the *Vicksburg* and ordered to duty at the naval hospital, Mare Island, Cal.

Woodward, J. S., P. A. surgeon, ordered to duty at the naval hospital, Mare Island, Cal.

Smith, H. L., P. A. surgeon, detached from the naval hospital, Mare Island, Cal., and ordered home to await orders.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended Dec. 14, 1910.

Brown, B. W., surgeon, relieved from duty at Vineyard Haven, Mass., and directed to proceed to Hongkong, China, for duty.

McCoy, G. W., P. A. surgeon, orders to proceed to Honolulu, T. H., revoked.

De Valin, H., P. A. surgeon, relieved from duty at Havana, Cuba, and, on the return of P. A. Surgeon J. S. Boggess, from leave of absence, from temporary duty at Chicago, and directed to proceed to San Francisco and report to Surgeon Rupert Blue for duty.

Thompson, L. R., asst.-surgeon, directed to proceed to Almena, Wis., on special temporary duty.

Brooks, S. P., acting asst.-surgeon, granted seven days' leave of absence from Dec. 12, 1910, under paragraph 210, Service Regulations.

Foster, S. B., acting asst.-surgeon, granted fifteen days' leave of absence from Dec. 17, 1910.

Tarbell, B. C., acting asst.-surgeon, leave of absence for thirty days from Dec. 1, 1910, revoked.

Board of medical officers convened to meet at Fort Trumbull, New London, Conn., Dec. 9, 1910, for the physical examination of cadets of the Revenue Cutter Service, to determine their physical fitness for promotion. Detail for the board: Passed Assistant Surgeon G. L. Collins, chairman; Assistant Surgeon H. J. Warner, recorder.

REFRACTING OPTICIANS, THE PUBLIC AND THE MEDICAL PROFESSION

James Thorington, M.D.

PHILADELPHIA

When opticians first applied to the state legislatures for regulation, the medical profession paid little attention, considering it a move to regulate a trade. Soon, however, the opticians commenced calling themselves "optometrists," and their trade a "profession"; i. e., "optometry." Then "optometry boards of examiners" took the right to ask medical questions and thereby made themselves a medical examining board. This fact was and is conspicuously evident as shown in the numerous medical questions asked in examinations given by these "optometry boards."

As soon as the medical profession had its attention drawn to this inroad of the non-medically trained on the field of the profession and the Aemrican Medical Association had passed resolutions[1] against further enactment of such vicious legislation, then such states as Massachusetts, Connecticut, Missouri, Texas, Ohio, Illinois and Maryland defeated the attempts of the so-called "optometrists."

It is important at this time to call the attention of the medical profession to the fact that refracting opticians have commenced their campaign. Petitions in favor of optometry legislation are being circulated among business men and physicians. The *Keystone Magazine*, for December, 1910, prints some of these petitions beginning: "To the Members of the Legislature: We the undersigned business men in your district, etc.," and "To the Members of the Legislature: We the undersigned physicians in your district, etc."

A new legislative campaign is to be conducted in order to get optometry laws enacted in the twenty-four states that have no such laws as yet.[2] Unquestionably, a number of these bills will be submitted to the legislatures in a number of states during the coming winter. So far from having the endorsement of any physician, they should be met with rigid disapproval and condemnation. There is no necessity or justification, either legal or economic, for any such laws, nor can any argument in favor of them be made which is not founded on sophistry.[1] Just as soon as "refracting opticians" receive "recognition" by the passage of an optometry bill, they immediately assume and advertise themselves as on an equality with members of the medical profession, whereas they are not medically trained, and the public is correspondingly deceived. This fact is well evidenced in an optician's circular at hand from which we quote the following:

> "We are to-day approved and accepted as STANDARDS by special optometry laws in twenty-four states which now recognize the practice of optometry equally with that of medicine."[3]

The optometry bill, so-called, legalizes prescribing for eyes by *men who are not members of the medical profession*, such as opticians, lens-grinders and jewelers. A very considerable proportion of defective eyes are the result of disease or abnormal conditions of the body. This being the case, a bill which licenses an optician to prescribe for conditions which can be *recognized and treated only after years of study and training* in medicine, may legalize the doing of an irreparable injury. Under the provisions of this bill, practically any man who has made and ground glasses for a period of two years before the passage of this bill can be admitted as a licensed refracting optician. Under this license, without even a smattering of medical knowledge, he can prescribe for the eyes of a man who is suffering from Bright's disease, or from rheumatic troubles, which diseases, and others also, directly affect the eyes, although he knows nothing about the particular disease or the general principles of anatomy, physiology and pathology. Moreover, this bill not only licenses a host of incompetents but it takes away from them all chance of prescribing correctly. Under the provisions of this bill, opticians are not allowed to put drops in their customers' eyes. It is the almost unanimous consensus of opinion among the text-book writers and ocular authorities that the majority of individuals under 35 years of age cannot have their eyes accurately measured for glasses without the use of drops.

By allowing non-medically trained persons to prescribe without this safeguard, inaccurate and harmful measures are legalized by statute. It is the province of the optician to grind lenses in accordance with the prescription of a trained doctor. He has no more business to prescribe for diseases of the eye or to attempt to treat abnormal conditions of the eye than has a shoemaker or glovemaker to treat diseases of the feet and hands. The medical profession, the better class of opticians and the majority of the thinking members of the laity *are opposed to these bills because they do not believe in* creating a doctor by statute rather than by study and training, and, especially, because the proposed bill not only legalizes incompetent men but also legalizes incompetent methods which are against the weight of all medical authority. For the above reasons the bill has failed to pass in a number of states, namely, Massachusetts, Connecticut, Pennsylvania, Illinois, Maryland, Texas, New Jersey, Missouri and Ohio. In most states where it has passed it was rushed through before the public had been aroused to its evils. It is to be hoped that no measures will become a law which will put the eyes of citizens beyond the pale of medical assistance.[4]

The purpose of this article is to endeavor to explain to *the general practitioner that it is* his personal duty to himself, his patients and to the medical profession, to oppose, in every way possible, the entrance into the practice of medicine of those who are not medically trained but who would practice on the body as a whole or specialize on any particular organ. As refracting opticians attempt to do the work of ophthalmologists, the great majority of general practitioners immediately get the impression that the passage of optometry legislation does not concern them, though it should be opposed by the ophthalmologists themselves. When it comes to an argument before committees on legislature, the members of the legislature conceive the idea, as general practitioners do not appear with the ophthalmologists in opposition to optometry bills, that it is a case of jealous rivalry. The true explanation of the successful passage of optometry bills in several states is found in the fact that the medical profession did not offer unanimous opposition. Disapproval has been left entirely to ophthalmologists. Naturally ophthalmologists have led the opposition, but only to explain, in detail, the folly of trying to treat the eye without taking the rest of the body into consideration, the impossibility of treating it adequately under such conditions, and also the irreparable harm that may follow from allowing non-medically trained individuals to prescribe for and diagnose diseases of this very important organ. If members of the medical profession had joined ophthalmologists in this endeavor to keep out of the profession those who are not qualified by a course of medical training and a state medical license, the refracting opticians would never have made any inroad into the profession. General practitioners could assist the cause of the medical profession if they would instruct their patients in the difference between an examination of their eyes by a specialist who is a doctor and one by the optician or jeweler who parades under the new name of "optometrist" and has never qualified in medicine. General practitioners also could assist by explaining to members of the legislature the interest of the commonwealth in having the eyes of the public, and particularly of children, protected by the members of the profession, and the importance of eyesight to the welfare of the community; also the fact that commercialism does not govern the practice of ophthalmologists, whereas it is a most conspicuous element in the work of the refracting optician.

This communication has been prompted especially by the reading of the excellent illustration of the dangers of optometry by Dr. Janeway.[5]

Surely every ophthalmologist can relate similar instances by the score. Only to-day, a telegraph operator was referred from a neighboring city with a history that he had purchased six pairs of glasses in the last eighteen months prescribed by opticians on account of a severe pain in the right eye. His eyes were found to be practically standard and no glasses necessary. Transillumination and inspection by a rhinologist revealed pus in the right frontal sinus as well as the right antrum, together with nasal polypi.

Instances of glasses having been prescribed by opticians when glasses should not have been ordered are not infrequently seen in private practice and in the clinic. This unfortunate condition of affairs can never cease until the profession demands protection for the citizens of the commonwealth; but the profession must unite and stay united in this demand. It would be a misfortune if the attempt should be neglected too long. If we do not bestir ourselves we shall find our profession sinking every year into deeper depths of restriction and degradation. Doctors do not need to regret the competition of each other, for; if this be fair, it is a stimulus rather than a hurt. The competition that really hurts is from the outside; it is the competition of persons who have never been trained or educated in medicine but who ignorantly attempt to treat patients and to heal the sick.[6]

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fifth Month—Third Weekly Meeting

II. Inflammations of the Skin (Continued)

Dermatitis Seborrheica: Symptoms, lesions, locations, course. Treatment.

Impetigo Contagiosa: Symptoms, lesions, characteristics. Diagnosis.

Dermatitis Herpetiformis: Symptoms. Varied lesions, course. Diagnosis.

Herpes Simplex: Locations, lesions.

Herpes Zoster: Lesions. Regional distribution. Treatment.

Lichen Planus: Symptoms and diagnosis. Treatment.

Lichen Ruber Acuminatus: Symptoms.

Acne: Age, frequency, characteristics, distribution, course. Acne punctata, a. papulosa, a. pustulosa. Acne indurata. Treatment: General, local, vaccine.

Acne Rosacea: Age, frequency, location. Rosacea, followed by acne. Third stage.

Sycosis Vulgaris: Sex, age, lesion, distribution. Treatment.

Psoriasis: Frequency, age, sex, heredity. Primary lesions, development, distribution. Psoriasis punctata, p. guttata, p. nummularis, p. circinata, p. gyrata. Treatment.

Pityriasis Rubra: Symptoms, diagnosis.

Pityriasis Rosea: Symptoms, diagnosis.

Society Proceedings

PHYSICIANS' CLUB OF CHICAGO

Regular Meeting held Dec. 2, 1910

Dr. James B. Herrick in the Chair

MEDICAL EDUCATION IN ILLINOIS

The Relation of the University to Medical Education

Dr. Edmund J. James, president of the University of Illinois: I became interested in the subject of education thirty-five years ago when a student of public administration in a German university. Organized society is greatly interested in the health of its citizens, because good health on the part of the body physical is the basis of any good health in the body politic or body social. The health of the citizens depends largely on a sound sanitary policy on the part of the state. A sound sanitary policy can not be carried out by the state without controlling and regulating in many ways the external acts of members of the society. The supreme importance of the medical profession in the history of human society is shown by the records of human experience. As the state developed a definite policy in regard to public health, it came face to face with two aspects of this very necessary development. First, a need of the results of medical education and research in order to carry out a definite policy in public health so far as it interfered with the regulation of the life of the people or the promotion of its common interests, and, second, the necessity of providing for the promotion of the health of its individual citizens outside of the realm of government interference. In order to carry out its sanitary policy, the state needed well-trained servants. The medical men who are going to be good advisers of the government in its sanitary policy, must be men of wide outlook and of great experience. They must be statesmen as well as physicians. Therefore the physician should be a man of liberal education. Twenty-five years ago Dr. William Pepper, provost of University of Pennsylvania, appointed a general university committee to take up the subject of the better integration of the professional schools of the university with the college and technical schools. I was associated with the subcommittee on the medical school, and recommended at that time that the university require for admission to its medical school a completion of the sophomore year in the college of liberal arts, and that a medical course of five years be inaugurated, the first two of which, corresponding to the last two of the college course, should be given to the study of the underlying sciences of medicine—chemistry, physics, biology, anatomy and physiology; that the last year should be devoted to hospital work and the two intermediate years to clinical instruction. I was convinced that, on the whole, the Germans had worked out the best scheme of medical instruction. This scheme consisted, first, in a very thorough, vigorous, intellect-developing secondary school course, extending in theory from the ninth to the eighteenth year of age, extending in practice from the ninth to the nineteenth or twentieth. With this preliminary education the student was permitted to begin his medical study. At that time it was possible for him to complete the entire course in a period of four years. That period has since been extended to five years. But even in that day the desirability of a student spending a year in hospitals immediately on passing the state examination for the practice of medicine was so generally felt that every aspiring youngster took such a year, if it were feasible for him to arrange it.

The future physician should be an educated and cultured gentleman, able to do his part as a thoughtful citizen of a democracy in the support and development of our social and political institutions. Physicians, if of the right type and inspired with the right ideals, may do more to raise social and political standards than members of any other profession.

He should be trained in a thoroughly scientific way. On the basis of this scientific training should be reared the superstructure of the practical application of this knowledge to the treatment of human disease. If the university will set before the community and insist on a standard of: first, a liberal education; second, a thoroughly scientific training; third, a practical training, then it will have done all that it can do toward preparing and sustaining a medical profession for this great work in the community and the state. I have been greatly pleased with every passing year to see some approximation toward this ideal. I believe that it is fundamental to any possible organization of medical education in this city or this state, that the State of Illinois as a unit should get behind this cause. The state should be supporting medical research and training just as completely and fully as it is supporting agricultural research and training, or engineering research and training, or legal research and training. If we all pull together and get the state to take this initial step, we shall have made the most important advance in this subject which has been thus far registered. For my part I am willing to sacrifice some other things in which I am greatly interested, or at least to postpone adequate provision for these things, in order to make this great step in advance.

---

[6] Whery, William P.: Before the Fort Wayne (Ind.) Medical Society, January, 1900.

If the commonwealth of Illinois will begin the policy of supporting medical research and medical training through the University of Illinois, I believe we shall have made another great step forward toward the time when the City of Chicago will be a recognized center of medical research, medical training and medical skill second to none in this country or, indeed, in the world.

How Can Illinois Obtain Higher Standards of Medical Education?

Dr. F. F. Wesbrook, dean of the College of Medicine and Surgery of the University of Minnesota: The health of the individual is not his concern alone; public health is the concern of the public. The state has an interest in every man's condition of health. The means which the individual employs to preserve his health or to cure disease is the business of the public just as much as is the financial standing required for taxation or compulsory schooling of the individual. The public should demand that it be protected against dishonesty, ignorance and incompetence on the part of those whom it would trust with the care of its personal and public health. Everything in which medicine plays a part is public business.

The physician should be a teacher. He should be trained what to teach and how to teach. The honest scientific medical man should always be able to make clear and logical to the layman the basis of his action or his advice in both private or public practice. To bring about results in the various lines of medical activity, we must supervise, first, the foundation of instruction preparatory for medicine. Second, there is the medical training. No matter what specialty is provided, a general knowledge of medicine is essential. Third, a further training in the particular specialty to be taken up.

As to pre-medical training, a knowledge of physics, biology and chemistry is very essential and the acquirement of a modern language is desirable. A knowledge of ethics and of psychology is useful; also a knowledge of the duties of the individual to society as a whole, and that means a knowledge of economics. This is necessary for the individual whose later studies are to be confined to pathologic or perverted structures and functions, whose practical work in life will consist in giving advice and treatment which may call for a readjustment of the habits of the individual. Since medicine of the future will require a great many trained specialists, the medical college should be prepared to offer all students some broad general instruction in many lines not heretofore included in the medical curriculum. The student should receive sufficient information to select wisely his future field of activity and acquire his knowledge and experience before entering that particular field. We must have special training for those who are to become specialists in certain branches, such as surgeons, medical health officers, medical school inspectors, sanitarians, superintendents of hospitals, and medico-legal experts. For all these specialties the university should be the clearing house. A university education is surely a state function, and a state university can and should be made the experimental arm of the state service.

In Minnesota our course has been increased, so that now we have two years of academic work and five years of medical work. All students who take the fifth year must spend it in a hospital approved by the state. These hospitals will be standardized and required to have certain laboratory facilities, to keep proper clinical records, and to do scientific work. We expect also to have courses in public-health and medical school inspection in the university. We hope to have a department of hygiene developed under the auspices of the medical college, and, if the need should arise for it, to have a school or college of public health as distinguished from a school of medicine.

DISCUSSION

Dr. Arthur Dean Bevan: I have been asked to open the discussion on these papers on the subject of the needs of Illinois in medical education, and the method of obtaining higher standards of medical education. Before we answer either of these questions, let us see what medical education means to-day not only here in Illinois, but in the United States and in the world. Medicine of to-day is a different proposition from what it was twenty years ago. At that time it was a mass of empirical facts, with very little scientific basis. To-day medicine is just as much a science as is chemistry, physics, or any of the sciences taught in a university, and it has developed into a great mass of useful knowledge. To-day medicine demands a thorough training in order to convert a student into a competent practitioner, a competent medical teacher, or a competent research man. That training as a minimum means a thorough secondary school training; a thorough training in the pre-medical branches of chemistry, physics and biology; a thorough training in the medical school, mostly laboratory work in anatomy, physiology, pharmacology and pathology; a thorough training in the clinical branches of medicine, obstetrics, surgery, and all the specialties. It means, furthermore, besides the course in a medical school, a training that the student can acquire only by spending at least one year as an intern in a hospital. That is practically the conception of medicine to-day in Germany, in Austria and in England. It is the conception also in most of our better schools.

Here, in this country, we have 130 medical colleges. A few years ago we had 166. Of these 130 medical colleges thirty-eight this year required of their students this preliminary training in the pre-medical sciences in addition to the four-year high school course. In these thirty-eight medical schools most of the students also obtain a year's experience in a hospital. I should like to see the hospital year made compulsory by every medical school.

I have shown the general conception of what medicine is to-day, and what a medical education means. Let us turn to the State of Illinois. All the medical schools in Illinois are located in Chicago, and this state has more medical schools than any other state or country in the world. Thre are now sixteen institutions in Chicago which turn out graduates who bear the title of doctor. Of these sixteen colleges, there are five which turn out doctors who legally, at least, are limited in their practice, and there still remain eleven schools which turn out doctors of medicine. Of these eleven medical schools, even on a very lenient marking only six could be included in Classes A and B by the Council on Medical Education which for nearly six years has been conducting an extensive study of medical education in the United States. Only three of these were accepted according to the Carnegie Foundation report. There are, therefore, on this very lenient marking five medical schools in Chicago which the Council on Medical Education could not under any circumstances include among acceptable colleges. These five medical schools are deficient in most or all of the following: Their preliminary requirements do not meet the standard of the medical practice act; their medical course is not strictly graded; the number of expert teachers is too limited or entirely wanting; adequate laboratory facilities are lacking or not used; important laboratory branches are not taught; dispensary and hospital clinical facilities are seriously deficient, absent or not used, or the school is to a large extent a commercial enterprise conducted for what profit or prestige there may be in it for its professors, or it is kept alive by the employment of misleading advertisements or by methods inconsistent with the maintenance of fair educational standards.

In other states reasonably high standards of medical education have been adopted and the present standards are strictly adhered to. A number of low-grade worthless colleges have been closed. In many other states there has been marked progress in obtaining better educational standards and better methods of regulating medical licensure. Illinois needs in medical education these things: fewer and better medical colleges; a more strict enforcement of the present requirements; a four-year high school education as a minimum standard for admission to medical colleges, and later a year or two of college work should be added to the preliminary requirement, this to include physics, chemistry and biology. As an additional safeguard, a thorough and practical examination should be required of every candidate for license. With these changes, the other problems concerning laboratory, dispensary and hospital facilities, would more rapidly approach solution. Illinois should not lag behind, but should be a leader in upholding right standards of medical education.

All this is not so much an indictment of the state board, which is shown by existing conditions to be inefficient, as it is an indictment of the entire educational system of the medical profession and of the people of the state. The solution of this problem is simple. We need a university education to provide educated medical men for the State of Illinois, and we simply demand the protection by an efficient state board against the worthless commercial medical college and the diploma mill.

Mr. **Arthur Herbert Wilde** (Northwestern University, representing President Harris): Northwestern University takes pride in its medical school. It was the first to establish a three-year systematic course of instruction, and also a four-year course, and it did this at great sacrifices. We all stand for higher medical education. That involves several things. First, it involves better prepared students. Northwestern University will require in the Fall of the coming year (1911) a two-year college course as a preparation for the medical course. These two years of college work will better prepare the student for his life work. Besides the well-prepared student, however, we must have well-prepared teachers. We want also more of the German patience and spirit of investigation. We must have complete laboratory facilities such as few schools possess at the present time. We must have certain enthusiasm for the work. I really believe we never shall prepare students and teachers and good laboratory men without the real spirit of higher medical education which is found in enthusiasm. Every school ought to have such laboratory equipment as the University of Chicago provides for Rush Medical College. It ought to have such endowment as Northwestern University has just received from Mr. Patten, who has given two hundred thousand dollars for the purpose of advancing medical research work, and every medical school should have also such enthusiasm as has been infused into the medical school of the University of Illinois by President James. Every school must have endowments. Medical schools are going to furnish a more expensive education, and this expense must be provided for by resources entirely outside of the fees of students. As to the request that is being made by the state university of the legislature Northwestern would say that an appropriation of one hundred thousand dollars is too small. If the state university takes up medical education in a thorough-going manner, it ought to ask a much larger grant.

The state university in its expansion work in medical education might provide lecturers to go from place to place and give lectures in preventive medicine, or first aid to the injured, or some preliminary steps that should be known in every household before a doctor arrives. Public sanitation and domestic sanitation should be taught the people as freely as they are taught agriculture. The City of Chicago should have a Pasteur institute or a Rockefeller institute of research, something as great as either. The resources for the establishment of such an institution in this state are as great as can be found anywhere in the world. The faculty or trustees of Northwestern University would welcome and appreciate as much as any one a college or institute of medical research within the present state university. We have a hearty interest with you in the progress of medical study and medical research, for we are here for the common purpose of enlightenment of the state, and we want to serve our day and generation in our way just as faithfully as we hope the other institutions will serve it in their way.

Dr. **Harry Pratt Judson**, president of the University of Chicago: When we consider the training of young men for medicine in the coming days, we must bear in mind that we have made a tremendous advance in science in the last few decades. Never in the history of the world has science moved so rapidly as now. A young man who is to be a physician must, therefore, have a sound training. A highly trained expert medical man is much more than a mere practitioner. He knows what is going on and how to lend a hand in the right place in the development of modern progressive society, and there will be, therefore, from the highly trained physicians of the future those who will be leaders of social development. There will be, I fancy, a smaller number of men whose genius lies along the lines of scientific medical research. Of course, physicians in general will do more or less of that, but there will be some few who are so trained and who are so expert, and whose enthusiasm is so great, that they will devote themselves, heart and soul, to this one fascinating, fruitful line of medical development. We need such men. In the years to come the advance of medical science will lie largely in the hands of such men. The amount of training to be given young men in these lines cannot be adequate with less than two years of college work as a foundation, and that I believe to be the minimum to-day in the minds of the best men who are connected with our medical schools. It is more important that medical schools should have a small number of properly prepared students than that they should have a large number of ill-trained students. The men who take more time in preparation will be the men of standing in the community.

Rev. **H. S. Spalding** (Loyola University): With regard to raising the standard of education, we believe in it. We look on Germany as the country that fits in perfectly with our system of education, and any standard that reaches toward that will meet with our approval. I want to say for Loyola University that we have as high ideals as any, and we are willing to work with you and for you in the enforcement of preliminary standards.

Mr. **W. D. Atmatter** (member of the Legislature of Illinois): This demand for a higher education is serious and ennobling. The king of the corn market (Mr. Patten) gave two hundred *thousand dollars* to Northwestern University for higher medical education, and I propose that the State of Illinois, which yields a larger corn crop than any other state, should at least give that much for this worthy purpose.

Mr. **Walter Clyde Jones** (state senator): I was surprised to find how important it is that the advocates of legislation and its opponents should be in Springfield. If the Illinois State Medical Society and other medical associations are *in favor of definite legislation*, it is important not only to educate public opinion so that the people will support the physician, but also to send men to the legislature to appear before committees of that body to educate them. It is impossible for any member of the legislature to grasp the important features of the innumerable bills presented unless specialists in the *particular* subject matter appear before the committees.

Dr. **G. W. Webster**, president of the Illinois State Board of Health: A few years ago I read a paper before the National Confederation of State Medical Examining and Licensing Boards, in which I proposed that the entrance requirements of medical schools should be one year of work in addition to the high school course. It was adopted. I had a conference at the same time with the Council on Medical Education of the American Medical Association in Boston, and told them what was to be done. It was generally understood that this one-year requirement was to be demanded as soon as the conditions would warrant it. In order to prevent the State Board of Health from demanding any such standard, the Legislature of the State of Illinois, at the last General Assembly, took out of the hands of the State Board of Health the power and authority to establish entrance requirements to medical schools. That standard was established by the people of the State of Illinois through the legislature, and was made a high school education. The State Board of Health has no authority or power to raise that standard in any way If you want to raise the standard to two years' work in college as an entrance requirement, in which I heartily believe, the first step is to repeal that part of the medical practice act which makes a high school diploma or a high school certificate an entrance requirement, and either leave it in the hands of the State Board of Health to make the standard what it should be, or else through the legislature make the standard such a standard as you demand.

Dr. JAMES A. EGAN, secretary of the Illinois State Board of Health, Springfield: There has been considerable said to-night regarding the State Board of Health's lack of enforcement of the law and of the structure of the law The State Board of Health has limitations of power which have not been brought out, neither has reference been made to the law under which the State Board of Health operates, except in the remarks made by Dr. Webster. Reference was made to the report of the Carnegie Foundation and to the work of the Council on Medical Education of the American Medical Association, whose reports differ on Illinois Mr Flexner came into Illinois and dropped off in Chicago in April, 1909, inspected thirty four schools in the state, inspected our medical schools, and condemned every school in Illinois, except one He even found fault with that particular school He condemned the College of Physicians and Surgeons, the Northwestern University Medical School, and other schools, and pronounced Illinois "a plague spot," for the reason that these schools prepared students in contravention to the state laws Of the schools condemned by him, four of them are now recognized by the Council on Medical Education of the American Medical Association Who is right, Mr. Flexner or the Council?

Taking up the matter of preliminary education, Mr. Flexner states that "scarcely more than thirty of the one hundred and fifty five medical schools of the United States enforce a definite entrance requirement" He states further that "similar conditions are repeated in Canada where out of the eight medical schools, three are without enforced preliminary requirements" Mr. Flexner's strictures on the teaching facilities are no less severe According to his report, only some thirty of the one hundred and fifty five medical schools 'are now fairly equipped with the necessary laboratories" "Fewer than thirty enjoy acceptable hospital facilities" He states further that only about twelve of the one hundred and fifty five medical schools of the country "have the clinical facilities that they need" It would appear from those statements that conditions found in Illinois are duplicated in other states

Dr JOSEPH ZEISLER I believe there are a great many who will agree with me when I say the Flexner report was in many ways one of the most important, one of the most helpful things, that could have happened to the progress of medical education in Illinois and elsewhere Flexner may have been a little bitter or severe in some instances, but was the report really unjust, when we compare the status of medical education in some of the best schools in this country with that elsewhere, as, for instance, in Berlin, Vienna, Bonn, etc? Do we not occupy a much inferior position, taking the average medical school in this country, as compared with European schools? I do not wish to enlarge on this thought, except to say that I believe this report, although it struck the school with which I am connected, was a good thing Let me cite one single instance of medical education in Chicago I have had occasion for four years to watch the medical career of a person who went through a college in Chicago which has the right to turn out doctors It was an evening school That person could not write English grammatically, nor German grammatically He is a most illiterate person, yet he was accepted by that college, passed through school by paying ten dollars every month, received the degree of "doctor of medicine," and came up for the state board examination Gentlemen, it is up to the state board, in the examination of persons who are absolutely unfit, to exercise that check which is absolutely necessary for the protection of the people of the State of Illinois I ask you, gentlemen, does the State Board of Health of Illinois ever exercise such a check? Is it not possible for such people to slip through on a written examination, which means very little indeed, and be let loose on the populace?

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

Nineteenth Annual Meeting, held at Richmond, Va,
Oct 31 Nov 4, 1910

(Concluded from page 2174)

Venereal Prophylaxis

Col L. Mervin Maus, M C, U S Army: The collapsible tube containing 25 per cent calomel and 75 per cent lard has been in use in the Department of the Lakes for several months with gratifying results The great prevalence of venereal disease in the Army led to the adoption of the "K" package, which was large and cumbersome, and which the men would frequently not use, but would throw away The collapsible tube has a capacity of one dram only, is small, compact and neat At the military tournament held in Chicago in July these tubes were supplied to the troops with the result that although they were in the city two weeks and surrounded by and having intercourse with the lowest class of prostitutes, not one of the men was infected, as demonstrated by a physical examination made after their return to their home stations During the time of the maneuver camp at and near Fort Benjamin Harrison, Ind I had another excellent opportunity to observe the effects of the tubes as regards prophylaxis The troops of the regular establishment at this camp consisted of twenty one companies of infantry, eleven troops of cavalry, one company of engineers and one half a company hospital corps Each man had a physical examination a few days previous to their arrival, and a test was submitted of those suffering from venereal diseases All the organizations were supplied with tubes and the men were instructed as to their use At the close of camp the following statistics were obtained 504 men had had sexual intercourse 1,301 times, using the tube after each contact Of these men three reported gonorrhea and of these one made contradictory statements and the other two claimed that they had used the tube but did not understand it In addition reports were received from 302 men who had had sexual intercourse 763 times and had not used the tube As a result one man contracted syphilis, twenty six gonorrhea and twelve chancroids The proportion of disease in those who used the tubes was ½ of 1 per cent, while among those who did not use them there was 13 per cent of infection These facts are exceedingly significant, and I recommend that the War Department issue orders to the following effect:

1 That monthly lectures on general military and personal hygiene be required of medical officers to commands, not only for the purpose of educating the officers and men on these subjects, but to enable them to preserve their health against contagious and other preventable diseases

2 That weekly physical inspections of companies or detachments be made by an instructed non commissioned officer, under the direction of the company commander, in undershirts, drawers and bare feet, immediately after the Saturday morning inspection for detection of personal uncleanliness, physical defects, condition of the teeth and feet and contagious diseases, all men suffering from physical disqualification or diseases to be ordered at once to the hospital for the action of the surgeon

3 That three antiseptic tubes be made a part of the kit of the soldier and that the men be instructed in their use, with such orders as may be necessary

4 That soldiers found suffering from contagious diseases rendered preventable by the use of the antiseptic measures prescribed, be regarded as having disobeyed a sanitary order and held guilty of violation of the sixty second article of war.

Pneumonia in the Mexican Army

Lieut Col Enrique Jurado y Gama, C M M M, director of the Military Hospital at San Luis Potosi Pneumonia is a serious disease which has not diminished in spite of the progress of medicine, among armies pneumonia causes great mortality, most often pneumonia effects a spontaneous cure by the successful struggle of the organism, hyperpyrexia and biologic and chemical changes produced in the tissues are the principal causes of the happy termination of the disease, prophylactic treatment of pneumonia is indispensable; there is no specific remedy for the disease; blisters and antimony salts are useless and dangerous; bleeding is a powerful resource that must be applied in many cases and in different stages of pneumonia; digitalis, strychnin and cardiac tonics have hitherto proved most successful; morphin employed in the form and under the circumstances I have detailed, namely, on the fourth or fifth day, hypodermically, mitigates the exaggerated irritability of the respiratory centers, soothes the orthopnea, subdues pain and slows the respirations, which become deep and regular.

The Navy and Tuberculosis

Medical Inspector C. T. Hibbett, U. S. Navy, described the U. S. Navy Hospital for Tuberculosis, located near Las Animas, Colo., on the site of the abandoned Fort Lyon, which now has a capacity of 225. He advocates the immediate extension of the sanatorium to quarters for at least 500 patients, and the enlargement of the power-plant to provide for a further extension to accommodate 1,000 patients. The extension of living quarters should be in the line of iron bed cottages for ambulance patients. He further suggests that the general government establish a tuberculosis colony on such site as may be carefully selected for all its official patients, this colony to embrace patients from the Army, Navy, Public Health and Marine-Hospital Service and Civilian employees. For this purpose a tract of several thousand acres would be required, and on this all sorts of farming procedures could be carried on. Educational systems should be substituted for militarism in the government of the institutions, and the men should be instructed as to their preparation for future farm or other open-air life.

Camps of Instruction

A lively discussion followed the reading of the various reports from officers of the organized militia on the camps of instruction in which they served. Lieut. Col. Junius F. Lynch, Surgeon-General of Virginia, was unsparing in his denunciation of joint camps of instruction, calling attention to the unprepared condition of the grounds, delays and inefficiency on the part of the quartermaster's department, the lack of working incinerators and the failure of civilian employees to operate the incinerators which were in working order. He claimed that too much was expected of the organized militia and too little was done for them. He believed that state camps were preferable, and that in these camps, instruction could be given by officers of the regular establishment.

Captain Henry D. Thomason, M.C., U. S. Army, in charge of the Medical Department of the Division of Militia Affairs of the War Department, expressed the opinion that the benefit to be derived from joint camps of regulars and militia were too patent to require demonstration. The massing of regular and volunteer troops is for the best interests of both, and by such instruction the unfortunate sanitary conditions which prevailed several years ago in volunteer camps are now avoided.

Africa and the Tsetse Fly

Major Louis Livingston Seaman, U.S.V., New York City, gave a public lecture illustrated by stereopticon views on "The Sleeping Sickness and a Hunting Safari in Africa," in which he described the horrible cruelties practiced in German territorial possessions in Africa, and spoke hopefully of the time when the "Cape to Cairo" railroad and British rule would put a stop to these atrocities. In certain parts of the country the tsetse fly, whose bite transmits the sleeping sickness from the sick individual to a well person, abounds, but only within 150 yards of rivers or streams, not going beyond these limits. The fly is dangerous only where the sleeping sickness prevails. It is the transmitting agency. The incubation period of the disease is seventeen days. The infected person or animal loses animation, becomes weak, enervated and emaciated, and finally the sense of pain is dulled or lost.

Bubonic Plague

Passed Assistant Surgeon William Colby Rucker, U. S. P. H. & M.-H. Service, narrated in a most interesting manner the fight made in California against the bubonic plague and the connection of the rat and ground squirrel with the disease. The ground squirrel is the reservoir of plague germs but does not transmit the disease to human beings, but by its bite infects the rat, which in its turn, acting as a germ carrier, bites and infects a human being, who in due course comes down with bubonic plague. For this reason he advocates the extermination of both rats and ground squirrels, but considers the latter as a far greater menace to the community, as ground squirrels exist throughout the country, as rats are everywhere found, and as all that is necessary to start a season of bubonic plague anywhere is an infected ground squirrel or human being. He deplored the fact that for commercial reasons the presence of bubonic plague in California was kept secret so long and asserted that the disease has been smoldering in the United States for a decade. In his opinion the ratproofing of buildings was the most important factor in the solution of the bubonic plague problem.

Major Paul F. Straub, General Staff U. S. Army, told of the experiences with rats and bubonic plague in Manila, where a force of 200 men was organized to trap and kill rats, millions of which were destroyed.

Paybill for Marine-Hospital Corps

The association adopted resolutions asking that the paybill of the United States Public Health and Marine-Hospital Service be revised to correspond with those already in force for the Army and Navy.

Iodin in Military Surgery

Col. Nicomedes Antelo, Chief of the Surgical Service at the Military Hospital, Buenos Aires, delegate from the Argentine Republic, who was delayed in reaching Richmond, had prepared a paper on the use of tincture of iodin in the surgery of war. It was read. The following were his conclusions: 1. Tincture of iodin is the ideal skin antiseptic in military surgery. 2. It is desirable to add to the individual first-aid package a receptacle containing tincture of iodin to sterilize the skin at the wound of entrance and exit. 3. In sanitary formations, when a surgeon is present, the field of operation, in case of need, should be sterilized by the Grossich method, that is, washing the region of operation on the previous evening, an aseptic application to be retained until the patient is placed on the operating table and the application of one coat of tincture of iodin at the beginning of the anesthesia, and another when the patient is anesthetized. The hands should be treated with tincture of iodin and then decolorized with sodium hyposulphite, Meissner's method, washing with soap and afterward with alcohol at 90 F. for five minutes, should be employed when it is impracticable to use the Grossich method. 4. The supply of tincture of iodin to the sanitary formations at the front, should be calculated in accordance with its use as described.

AMERICAN ASSOCIATION FOR THE STUDY AND PREVENTION OF INFANT MORTALITY

First Annual Meeting, held at Baltimore, Nov. 9-11, 1910

(Concluded from page 2177)

Municipal, State and Federal Prevention of Infant Mortality

Dr. William H. Welch, Baltimore: The United States is particularly far behind other countries in organized attempts to solve the problem of infant mortality. The apathy in this respect is another of the many examples of the way this country suffers from the lack of a thoroughly organized and complete bureau or department of public health under the national government. Municipal health boards have only recently, and only in a very few instances, taken up work in this field with any energy or thoroughness. Work begun by private initiative can often be taken over later more successfully by municipal or state boards of health than if they were called on to initiate the undertakings. It is important to train and supervise midwives and regulate their practice. Between 80 and 90 per cent. of births in a certain class of the population are attended by midwives. The Maryland midwifery act specifies qualifications and requires registration. Its administration is in the hands of the State Board of Health. A school for the training of midwives is a great need in this country.

Report of the Committee on Birth Registration

Dr. Cressy L. Wilbur, Washington: Much has been done and can be done in the absence of reliable vital statistics to cut down the infant death-rate, but accurate vital statistics are indispensable to the development of an intelligent campaign of prevention. The paramount duty of an association for study and prevention of infant mortality to build up such an "intelligence department" is to give true and exact information for the guidance of active workers in this field of preventive medicine. Infant mortality cannot be stated, as adult mortality is, in ratio to the enumerated population. The infant death-rate must be computed as the ratio of number of deaths of infants under 1 year of age (exclusive of stillbirths) for every 1,000 children born alive. Births must therefore be registered as regularly as deaths. Because we do not register births in the United States, it is impossible to compute a death-rate for babies in any state or in any city in the United States in such a way as to be comparable with the infant death-rate of any other civilized country. Accurate vital statistics of infantile mortality are needed for individual cities, rural districts, states and nation as a whole. Accurate statement requires complete and satisfactory registration of both births and deaths. There is accurate registration of deaths for only about one-half of the total population of the country (55.3 per cent.) and even in states in which there are fairly good registration laws, the equally important or even more important registration of births is neglected. The blame is sometimes placed by health officers on physicians or midwives for failing or neglecting to register births. This is unfair, because the physicians and midwives are not charged with the enforcement of the registration laws, but to obey them. Only a few states have even approximately complete registration of births (90 per cent., or one birth omitted for every ten that occur). Tentative list, New England, Pennsylvania, Michigan and District of Columbia, Ohio and Missouri. Enforcement of the law an essential part of effective administration of any system of birth registration. Model law in force in Pennsylvania since 1905; Ohio, 1908; Missouri since 1909.

What the Obstetrician Can Do to Prevent Infant Mortality

Dr. J. Whitridge Williams, Baltimore: The obstetrician should care for the mother and child not only at the time of labor and the few weeks immediately following it, but should observe the patient throughout the entire course of pregnancy, and as long after delivery as may be necessary to insure her return to normal health. Pregnancy ending in an abortion or by the birth of a dead child is an economic and biologic waste. The live-born child must be put in the most favorable conditions for its further development. The obstetrician may prevent infantile mortality by prophylactic measures before and during pregnancy, by the proper conduct of labor, and by the care of the child during the first month of life.

The Duty of the Municipality in Relation to Infant Mortality

Dr. Joseph S. Neff, Philadelphia: Diarrhea and enteritis are terms suggesting no alarm, yet in 1909, in the registration area of the United States in every 100,000 population; 72.3 infants died from these causes, 70 per cent. of these deaths being preventable. In the same year tuberculosis, pneumonia and diarrhea and enteritis caused 43 per cent. of the total deaths from disease without creating any marked public comment. Assuming the mortality in the non-registration area in the United States for 1909 to be the same as in the registration area, much more publicity was given to 19,419 deaths from typhoid fever, in that year's record, than to the mortality of infants, which was 253,268, or a much larger mortality than in any other age period or from any single disease. More time and money has been devoted toward preventing the spread of tuberculosis of the lungs than toward any other health effort, yet the total mortality from that cause last year was 50 per cent. less than the mortality among infants. For economic reasons there is no better investment for a commonwealth than to care properly for the defective classes and provide institutional care for the feeble-minded women during the child-bearing period. I favor the passage of sterilization laws to prevent the illegitimate propagation of the species of the criminal and defective classes. The necessity for safeguarding against an inferior or polluted milk supply is evident. As an example for the benefit of the city councils, a campaign of education was conducted in Philadelphia in the section of the city thickly congested with a foreign population. Through a corps of physicians and professional nurses home instruction was given mothers in the care and feeding of their babies. Results showed 36 per cent. less infant mortality in the districts covered by the municipal nurses than in the rest of the city as compared with the preceding year, notwithstanding the fact that last summer was the most trying one on babies from weather conditions the city has had with one exception in thirteen years.

The Necessity for More Minute Study of the Causes of Infant Mortality

Dr. John S. Fulton, Baltimore: The report on infant mortality for 1908, given by the United States Census Bureau, shows that the total deaths in the registration area, under age of 1 year, were 136,432. Causes of earliest death were prematurity, malformation, injuries sustained at birth and syphilis. Convulsions are charged with 5,295 deaths under 1 year. Next come 76,903 deaths caused by whooping cough, diarrhea, diseases of the mouth, suffocation, acute bronchitis, broncho-pneumonia, measles, tuberculous meningitis, meningitis, diphtheria, scarlet fever, tetanus and pneumonia. Total number of deaths from diarrhea was 37,049. Largely through assistance of confederates, bronchitis and pneumonia killed 19,144 infants in the registration area in 1908. A study of sickness month by month, through the first year, will show that nurslings are naturally better defended than their older brothers and sisters from the infections of childhood, and due advantage being taken of this circumstance, these infections, together with bronchitis and pneumonia, can practically be ruled out of the mortality of the first year.

A Statistical Survey of Infant Mortality's Urgent Call for Action

Mr. Edward Bunnell Phelps, New York City: Infant mortality approximately averages about 130 deaths to each 1,000 living births in all civilized countries on the basis of the latest available official data—being almost half again as high in certain European countries. This single fact, the death of at least thirteen out of every 100 babies born alive, constitutes the moving cause for the organization of this Association and similar movements now taking shape in various foreign countries. Owing to the lack of national statistics of births, except in census years, the annual infant death-rates for this country as a whole are not yet available, but there can be little doubt that the infant death-rate in this country has undergone at least a slight decrease in the last decade. Despite that probable fact, as official returns for the city of New York and the state of Connecticut demonstrate, in the third quarter of the current year the infant death-rate of 169 per 1,000 births then registered in the city of New York was precisely the same as that for the corresponding quarter of 1909, and the infant mortality of the entire state of Connecticut was 193 per 1,000 births in the third quarter of 1910, as against 192 per 1,000 births in those months of 1909.

Medical Prevention of Infant Mortality

Dr. L. Emmett Holt, New York: Excessive infant mortality is one of the large problems of society. It can never be completely solved because its two most important underlying causes, poverty and ignorance, will never be removed. At most only partial success is possible. Desired results can be reached only by the cooperation of many agencies. At the outset there is needed an intelligent and comprehensive view of the subject as a whole. This will make it possible to separate the causes which are preventable from those which are, in a sense, inevitable. We must first know the facts of infant mortality. This means better vital statistics in the city and country. We need especially complete birth reports, more accurate statements regarding the causes of death, especially in stillbirths and deaths in the early weeks of life. What is more difficult to get at is the causes which underlie these facts. This must be the work of the medical profession. It is only by discovering and influencing the underlying causes that marked results can be accomplished. It is the duty of the profession to concentrate public attention on the large factors which contribute to infant mortality, to insist on a more thorough study of these and suggest means by which they may be reduced. A broad, unified, comprehensive plan should be made at the outset in which all philanthropic agencies shall work together for the accomplishment of the main purpose.

Do Medical Schools Adequately Train Students for the Prevention of Infant Mortality?

Dr. Ira S. Wile, New York: Medical schools fail to give adequate training of medical students to enable them to fight the conditions giving rise to such a tremendous portion of the total mortality. Pediatrics is, at present, treated generally under the head of general medicine, though infant mortality involves many conditions which are not comparable with any ailments in adult life. It is generally admitted that one-half of the infant deaths are preventable. Medical schools do not give sufficient attention to the subject of hygiene or prophylaxis. Education is conceded to be the greatest factor in the prevention of infant mortality. Medical schools do not so train men as to make them capable of teaching nurses, interns, mothers or philanthropists. The Council on Medical Education failed to make adequate provision for hygiene or pediatrics in mapping out its ideal medical curriculum. There is a total failure to grasp the underlying social conditions on which infant mortality rests in large part and which physicians must be able to attack in order to prevent infant deaths. The social causes of death are not considered in medical schools. The present teaching of pediatrics is inadequate, the teaching of hygiene is still more lacking, the teaching of the relation of infant diseases to social conditions does not exist. The problems of prevention lie in these three fields and, as they are scarcely entered by medical schools to-day, there results the constant addition to the medical profession of men ill trained and incapable of being of great service in the work of preventing infant mortality.

DISCUSSION

Dr. William H. Welch, Baltimore: There is no question that the great need of our medical schools in this country is the establishment of satisfactory training in preventive medicine and public hygiene. We hear equally urgent pleas for almost every subject in medicine. We cannot send the student out adequately trained in any branch; the most that we can hope to do is to give him broad general principles and put him in a way to continue his education. He will not by any possibility be trained in public health or in any aspect thereof when he passes from the medical school, but he should know the importance of the subject, and if his interest lies in that direction, he should be in a position to carry out his functions. But it would be a great misfortune if a medical school without adequate facilities pretended to train men in public health. These results cannot be obtained without large resources.

Dr. Frank Warner, Colorado: I was surprised to learn that the record of the midwife in New York in the prevention of ophthalmia neonatorum is better than that of the physician. If the result of the teaching already instituted is that the physician does worse than the untrained midwife, what may we look for when the teaching is still greater?

Dr. Baker: One reason why there is less ophthalmia neonatorum among the New York midwives' cases than among the physicians' cases is the fact that during the past two years silver nitrate solution has been used by the former in the eyes of all new-born babies, and as far as I have been able to investigate, this practice is not so prevalent among the medical profession.

Dr. W. D. Hoskins, Indiana: It seems to me that some further explanation might be made of the statement that teachers of diseases of children are the ones deserving of criticism for the lack of time and opportunity in the courses. I rather question the wisdom of such criticism. It is not that these teachers would not like to have more time, greater facilities and better opportunities to elaborate on these preventive measures, but it is impossible to accomplish better results in a short time and with limited means. As far as I have been able to observe they are careful, skilful men who comprehend the magnitude of the social problem, as well as the details of their teaching. And, as far as I have been able to observe, the students who are going out comprehend these things in a greater measure than we might infer from Dr. Wile's paper. As with other specialties, it is impossible to give the department of pediatrics all the time wanted, but a creditable showing is being made by practically all of the medical schools. As far as I know, Johns Hopkins is the only one in which the subject is elective.

Dr. Ira S. Wile, New York: I trust that Dr. Welch has not misunderstood that I am advocating that institutions give courses in public health simply to teach how to prevent infant mortality. Since between 40 and 50 per cent. of infant mortality is preventable, the stress of work should be put on preventive medicine. As to there being less ophthalmia among midwives than among physicians, this may be due to the fact that pediatrists do not talk so much about this subject. As to the criticism of Dr. Hoskins, I found that the average time given in a course of pediatrics was sixty hours, the greatest 120 hours, the smallest none. I am not blaming individuals; I am criticizing schools that fail to give this course in their curriculum.

Erroneous Ideas of Infant Mortality and Methods of Reducing It

Dr. S. W. Newmayer, Philadelphia: In most campaigns there is an effort to educate the mother with a well child, the care of the sick infant being overlooked. Every department of health should have its "publicity bureau," under the charge of a competent newspaper editor, one with at least a working knowledge of medical subjects, especially of those which relate to public health. Gastro-enteritis, which causes most infant deaths, is chiefly due to improper feeding. The feeding of the infant is the responsibility of the physician attending at birth, but is more often left entirely to the mother. The efficiency of health departments in reducing infant mortality would be greatly augmented by the employment of a corps of visiting nurses, or of specially trained physicians, who could give the necessary instruction to mothers in their homes or who could give individual care to the sick babies. The objections made to such measures, on the ground of paternalism, are unfounded. If the infant is not receiving proper nourishment and care, whether through ignorance or neglect, it is the duty of the municipality to give all the personal care and attention it can give.

Vaccine Treatment in the Prevention of Dysentery in Infants

Dr. William Palmer Lucas, Boston: In the series of cases studied at the Infants' Hospital, Boston, 100 infants received vaccine in graded doses, from one to three injections being given to each patient of a vaccine made up of the Flexner-Harris dysentery bacillus. The vaccine was not used as a means of treatment, but simply as a preventive measure. All of the patients were infants who had had no sign of dysentery at the time of receiving the injections. The reactions in these cases were studied, and a close watch was kept to see if they developed any acute intestinal trouble throughout the summer. One or more bacteri ologic examinations were made of each of these cases, and also a parallel series of cases was studied bacteriologically to see how frequently the dysentery organism occurred in this class of cases. The work is merely suggestive and no definite conclusions can be drawn. No bad results were obtained.

The Education of the Father an Important Factor in the Prevention of Infant Mortality

Dr. William Palmer Lucas, Boston: We must not overlook the importance of educating the fathers, especially of the poor, congested districts, along the lines of the principles underlying the prevention of infant mortality, for, as the social worker has learned, the father in the families of our foreign population is the actual head of the household. There were several classes formed during this past year under the direction of the Milk and Baby Hygiene Association for the instruction of the fathers in the districts in which several of the milk stations were situated. These met with a fair amount of success and this form of work promises to be of considerable value in gaining the confidence of the family which is of great help in obtaining the best results in a case of sickness among them.

DISCUSSION

Dr. Herman Schwarz: With regard to the education of the fathers, the following figures are interesting: In 210 families where both parents could read, 710 children were born, and there were 135 deaths, or 190 deaths per thousand born; where the parents were illiterate, the death-rate was even higher, so it is shown by statistics that the care of the children is better where one or other parent, or both, could read; it does not seem to make much difference which parent can read. In families where neither parent can read and where there is intense ignorance, the death-rate is much greater.

Mrs. William Lloyd Putnam, Boston: I believe that the fathers are ready for education. Last year a committee of the Municipal League carried on an exhibit every afternoon and evening in Boston. We had a mother with her baby, a doctor and a nurse, and the doctor lectured to the crowds that collected. At times it was interesting to see that there were three or four times as many young men present as women, evidently young fathers. It was evident that these young men were there because they were fathers and anxious to learn.

The Possibilities of Maternal Nursing in the Prevention of Infant Mortality

Dr. Thomas S. Southworth, New York: Maternal nursing not only offers new-born infants the best chance of surviving the first year, but lessens the mortality of succeeding years. There are sufficient and insufficient reasons for putting the baby on the bottle. Few women refuse to nurse, but too many who are anxious to do so are prevented from doing so by ignorance or bad advice or misinterpretation of the baby's condition. The stools and behavior of infants getting scanty breast milk lead to a mistaken belief that the milk is bad. Early weaning of infants is unjustifiable until intelligent effort has been made to build up the mother and utilize the breast milk as a part, if not all, of the infant's food. There is no adequate investigation and little scientific or popular knowledge of the function of human lactation. Responsibility for this rests on the state, the educator, and largely on the hospitals for infants and nursing mothers, for these latter do not, as a rule, make the best use of their opportunities for encouraging and disseminating knowledge on this subject.

Method of Determining the Influence of Medical Philanthropy in Reducing the Morbidity and Mortality of Infants

Dr. Henry L. Coit, Newark: Agencies employed for the reduction of infant mortality have directed their efforts along different lines. These are: medical work in hospital wards and clinics where infants are treated; milk dispensaries and consultations independent of hospital supervision; philanthropic association work aside from hospitals and dispensaries; municipal agencies which employ nurses to teach infant hygiene in the home, and state and federal agencies which, by ordinance and law, attempt to influence mortality by determining statistics, regulating the food supply and making more sanitary the homes of the poor. The value of each of these methods of work and their effect on mortality have been variously estimated by those who are engaged in this work with a tendency to over-estimate the value of the special feature in which they are interested. When these various methods of work are combined under the same direction or supervision, it would be desirable if some simple system could be formulated for the collection of facts and statistics which would show the *relative value of each kind of work in its* influence on the reduction of infant mortality. Statistics are of no value unless they determine how far we have influenced or improved the conditions affecting the care, the physical condition and the living powers of infants. The percentage plan of scoring has been employed to determine the status of *social, scientific and commercial investigations;* but no comprehensive scoring plan has been adopted which would include in its scope all the conditions which influence the care, the physical condition and the living powers of the infant. The method herewith presented, which consists of a statistical score card, is designed for a careful collection of facts to determine the influence of environment, of management, of nourishment and of morbidity on the viability of the infant and by a graphic chart to show the improvement in viability during a given time through the activities of medical philanthropy and educational work directed to the betterment of the conditions which influence infant mortality.

Educational Prevention of Infant Mortality

Dr. Helen C. Putnam, Providence, R. I.: In a democracy, governmental, medical or philanthropic prevention of infant mortality must have intelligent popular cooperation to be successful. This means popular elementary education in the essentials of hygiene, sanitation and the laws of life. Public schools are the universal agent for laying this foundation and we are dissatisfied with their results, our vital statistics being the test. The annual reports of most normal schools emphasize the claim that they are professional. Their health practices and instruction are no better than we find in public schools. They have the same humanitarian need to be standardized as medical schools. Their annual reports exaggerate the value of their instruction in the foregoing respects as often as medical schools exaggerate, according to the Carnegie Foundation Report. Not one of the forty normal schools studied had well-balanced courses in healthfulness of school and of home, in health of the individual and of the community. Their work is largely determined by examinations for licenses to teach. Ninety-three per cent. of the questions are on anatomy. Less than 7 per cent. are on function or on health. I have seen examination papers with none. Students say frankly they do not think the instruction worth while. Examining boards—the pace-makers—can promptly bring normal instruction up to modern needs by suitable questions and tests formulated by health officers, biologists, and school or visiting nurses.

Resolution

The following resolution was passed by the Association: Healthy parents, right customs and wholesome environment being essential factors in preventing infant mortality, be it

Resolved, That boards licensing teachers for public schools should give as detailed tests in elementary hygiene, sanitation, and biology as are given in mathematics or language.

The Study of School Sanitation and Hygiene

Dr. Herbert Burnham Davis, Pennsylvania: Good parentage is sometimes handicapped by school as well as by home conditions. Dental examinations of children in the practice school by a dentist and medical examinations by a physician are attended by our normal students, who assist in making the records. Through discussion and study of these records an attempt is made to plan a simple outline for examinations by the teacher in an isolated school. Practical demonstrations are given in using disinfectants, cleaning floors, ventilating. Study of backward children in a psychologic clinic is important, as is that of mechanical factors in school seats causing restlessness and physical defects. All this work has a definite practical direction by practical methods. Normal schools should require all this from every pupil and also studies of sanitary law, sex instruction in public schools, industrial hygiene, and hygiene of the home.

DISCUSSION

DR. HELEN C. PUTNAM, Providence: I have visited at least 600 schools and there were only 210 thermometers, 70 of which were broken and out of order, and the remaining registered in winter weather from 71 degrees to 80. Also bear in mind that there are schools in this country, practice schools connected with normal schools, which are sending out thousands of trained teachers, where I have found the floors oiled with an oil that was put on thick to hold the dirt that fell on them. While it kept down the dust, this was educating the child in an atmosphere filled with the odor of oil, and teaching him to go into the schools without cleaning his feet. These are indications that standard methods of teaching should be urged in this Association.

DR. C. E. A. WINSLOW, New York: From the sanitary standpoint, teachers should have a fundamental training in biology and physiology; second, there should be a course on the relation of the individual to his environment in the spread of disease; third, there should be a practical course, such as has been so admirably described, in school hygiene and sanitation. A method of determining the carbon dioxid in the air should be taught. This course should include also inspection of school buildings, a study of the waste disposal systems, the lighting, desks, etc., of as many schools as possible. We have gone in these campaigns for public health about as far as we can go without the aid of the teachers in the public schools. Some of the schools have already made great progress in solving this problem.

MISS MOORE, Trenton: Every year I find in my class in biology students who are addicted to certain habits, such as sucking the end of their pens or pencils, chewing the finger nails, etc. A good deal of discussion was given in the class of the possibilities for danger in such practices, but frequent lapses would occur. With the cooperation of the class, some experiments were tried. The relation of germs to disease was illustrated by drawing the chewed end of a pencil across the surface of agar, or by making thumb prints on the agar, etc. The results were demonstrated. Altogether, the demonstrations served their purpose in not only emphasizing and giving force to the discussions on this subject, but in introducing into the discussion an element of reality, of tangibility—an element very desirable, as I found, in our campaign against dirt.

DR. HELEN C. PUTNAM, Providence: The chief organisms in dust, those that cause disease, are rather promptly killed by air and sunshine. In the public schools with high temperatures and dusty atmospheres, tuberculosis is invited. The death rate from tuberculosis among teachers is very much above that in any other profession. Reports show that between one-fourth and one-half of the children have latent tuberculosis. Children who die from scarlet fever or diphtheria, where tuberculosis is not suspected, have by examination been found to conceal tuberculosis. The Roentgen ray and the tuberculin test also often reveal latent tuberculosis.

DR. C. O. PROBST, Columbus, O.: It is a question whether the school teacher will be able to fulfil all that we expect of the public schools in teaching health matters. I am inclined to think that we must have a specialist, a school physician, who must have medical education and also special knowledge of the child. I do not believe it possible for a public school teacher to recognize beginning cases of scarlet fever, diphtheria, or other contagious disease. There should be a daily inspection of the schools, and a school physician could accomplish much. I think the day will come when in every large school building in this country, there will be, along with the superintendent, the school physician, devoting all his time and attention to looking after the physical welfare of the child, even to the extent of interrupting its studies when he considers it necessary for the child's health.

The Study of Home-Making

PROF. FLORA ROSE, New York: Home economics where well taught goes straight to the root of infant mortality. It instructs directly, openly, specifically in those things relating to the welfare of homes. Our educational system should consider every pupil as a potential parent. We have normal courses in caring for and feeding babies; we consider mortality rates as affected by abnormal industrial conditions, disease, heredity, environment. We have propaganda work through lectures even to remote country districts; and through free literature dealing with care of infants and of homes. Many urgent requests for instruction in these subjects come to departments of home economics. When graduates are more numerous they will effectively mould public standards of home-making and parenthood, and they are already becoming valuable instruments in preventing infant mortality.

PROF. ABBY L. MARLATT, Wisconsin: In Wisconsin "humanics" comes in the junior year when the students have laid a foundation of bacteriology, biology and physiology along with their household management. We discuss heredity, the influence on the child of alcoholism and other drug habits in the parents, the relation of social evils and their diseases to infant and child mortality and degeneracy; methods in different countries for saving babies; the French system of pensioning expectant and new mothers so that they may be properly housed and fed; education for better parenthood, prevention of vice and of drug habits, of bad housing, and political mismanagement that allows it. We also discuss adolescence, child labor, and vital statistics as related to home-making. The central thought of our four years' course is—conservation of human life by improving homes and cities and individuals so that future generations may reach higher levels of efficiency than those preceding them. The University of Wisconsin is at the head of the state's public school system, and this department is closely related to "domestic science" for the children which we consider very much more than "cooking and sewing."

DISCUSSION

DR. CHARLES FORD LANGWORTHY, Washington: In every state there is an agricultural college which is quite largely supported by government funds, and of the fifty odd colleges of that sort in the United States two-thirds give courses in home economics. It seems to me that of the problems concerned with infant mortality none could be more important than these matters of proper food. We must have fundamental facts available regarding nutrition, and our work has been to gather these facts. This information has been published in leaflets. We have been trying to perfect an instrument with which to study the relative ease of digestion of different foods. Another thing which I should like to do is to study the great problem of overwork, and to study more thoroughly the problems of increasing the efficiency of the housekeeper so that she would not be broken down from overwork.

The Study of Biologic Science

PROF. JESSIE PHELPS, Michigan: We have offered for three years a course in physiology of sex and development. Such biologic instruction is to establish through teachers and schools higher ideals of parenthood. Two hundred and fifty-one have elected it, and nearly all are teaching. The plan is to give scientific setting for personal and sex problems which every teacher has to meet in school. About one-half the time is spent on life histories of familiar plants and animals from lowest to highest, including man, so that the principle of evolution is deeply instilled. Much time is given to the embryology of the chick with demonstration of incubated eggs. This method allows exposition of all the cardinal doctrines of biology and gives a setting for the facts of human reproduction, fundamental character of reproductive processes throughout Nature, place of individual in race, advantages of sex, origin of sex, heredity, continuity of germ plasm, and evidences of evolution. The basic facts of embryology are necessitated by such a treatment, and the way is thus opened for introduction of the more important topics of human sexual hygiene, standards of courtship and marriage, parenthood, eugenics, diseases spread by prostitution, children's vices, and instruction of children in matters of sex. Graduates are urged to form parent's clubs. They report finding applications for Nature study not before realized, and appreciating much better the far-reaching effects of school sanitation and children's habits.

Dr. Willard S. Small, Washington: Vitality, endurance and healthy functioning are what schools must promote. Biologic science should be studied for this purpose through every year of the normal course, whether two, three or four years. Emphasis should be on processes rather than on anatomy. Study of school hygiene must have it as a background to be effective. Normal school-room practices and care of buildings must be models of hygienic observance as part of the preparation of the teacher. Physical health profoundly affects moral health.

Dr. Llewellys F. Barker, Baltimore: The healthiest mode of approach to questions related to sex is through a study of plant and animal life. The two great factors of life, heredity and environment; can be brought before students in a wholly unobjectionable way, and the analogy of human life is so obvious that the principles learned will almost surely be transferred in due time by the learner to the human domain. Observation and experiment, even if limited to a few fundamental points, will be far more fruitful than didactic lectures. Let the teachers-to-be observe for themselves the influence of external conditions in causing changes in the structure of plants and animals, let them note the responses of living substances to heat, light, oxygen, food substances, poisons and infectious agents, and they will quickly realize the importance of a well-regulated environment for the welfare of human life. Again, let them study pollen and ovule microscopically, observe the process of plant fertilization, and the development of the plant embryo, or permit them to watch frogs' eggs, fish eggs, hen's eggs, and to follow the embryos through their various stages and you have chosen the easiest way to initiate them normally into a knowledge of the mysteries of sex, of impregnation and conception, of birth and development. Experimental hybridizing in sweet peas or in colonies of mice quickly opens the mind to the significance of heredity, and surely nothing is more likely to awaken conscience to the duty and privilege of the human race, of improving the quality of the children born than some acquaintance with the laws of heredity, and especially with the rules of Mendel regarding the inheritance of particular qualities.

If the teachers of our schools knew that drunkards, lunatics, idiots, prostitutes, and habitual criminals are such because in the majority of instances they have been born with defective nervous systems; and if they knew that such drunkards, lunatics, idiots, prostitutes, and habitual criminals are more likely to breed their kind than to have healthy offspring, we should have taken a large step forward in that education of public opinion, which will be necessary before we can pass laws which will prohibit parenthood to the notoriously unfit. If the same teachers knew that a family record of "good stock" on the husband's side and on the wife's side is the best guarantee for the birth of physically, mentally and morally healthy children, they could do much toward the development of that sane opinion about marriage which those who have the good of the people at heart hope may soon displace the abnormal ideas now prevalent, not only among young people, but among their parents, who should know and teach their children better.

DISCUSSION

Dr. Helen C. Putnam, Providence: I must take issue with Dr. Barker on one important point. He emphasized the need of teaching women teachers and I think that most educational efforts teach women more than boys and men; I think the balance should be even. In the public schools we must make a special effort to have the boys receive something comparable to what the girls receive in their domestic science work, in order that the boys may become good home makers also.

State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, January 10. Chairman, Dr. W. H. Sanders, Montgomery.

Arizona: Phoenix, January 3-4. Sec., Dr. Ancil Martin.

Colorado: Denver, January 3. Sec., Dr. S. D. Van Meter, 1723 Tremont Place, Denver.

District of Columbia: The District Bldg., Washington, January 10. Sec., Dr. George C. Ober, 125 B St., S.-E.

Illinois: Coliseum Annex, Chicago, January 11-13. Sec., Dr. J. A. Egan, Springfield.

Indiana: 120 State House, Indianapolis, January 10-12. Sec., Dr. W. T. Gott.

Minnesota: State University, Minneapolis, January 3. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg., St. Paul.

New Hampshire: State House, Concord, January 3-4. Regent, Mr. Henry C. Morrison.

New Mexico: Santa Fé, January 9-10. Sec., Dr. J. A. Massie.

New York: New York City, Albany, Syracuse and Buffalo, January 31 to February 3. Chief of Examinations Division, Mr. Charles F. Wheelock, Albany.

North Dakota: Grand Forks, January 3-5. Sec., Dr. H. M. Wheeler.

Oklahoma: McAlester, January 3. Sec., Dr. Frank P. Davis, Enid.

Oregon: Portland, January 3. Sec., Dr. E. B. McDaniel, Electric Building.

Rhode Island: State House, Providence, January 5. Sec., Dr. Gardner T. Swarts.

South Dakota: Aberdeen, January 11-12. Sec., Dr. F. W. Freyberg, Mitchell.

Vermont: Montpelier, January 10-12. Sec., Dr. W. Scott Nay, Underhill.

Washington: Spokane, January 3. Sec., Dr. F. P. Witter, 207 Traders' Block.

Wisconsin: Milwaukee, January 10-12. Sec., Dr. John M. Beffel, 3200 Clybourn St.

South Carolina June Report

Dr. A. Earle Boozer, Secretary of the State Board of Medical Examiners, reports the written examination held at Columbia, June 14-16, 1910. The number of subjects examined in was 18; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 105, of whom 61 passed and 44 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Atlanta College of Physicians and Surgeons	(1910)	79, 79, 82, 83

Book Notices

A Text-Book of Physiology. By Isaac Ott, M.D., Professor of Physiology in the Medico-Chirurgical College of Philadelphia. Third Edition. Price, $3.50 net. Cloth. Pp. 891, with 393 illustrations. Philadelphia: F. A. Davis Co., 1909.

The order in which the author has arranged the subject matter in this book is commendable. The first chapter is devoted to a full discussion of the structure and function of the cell, including its various metabolic changes, and reproduction. The succeeding chapters take up in order the chemical constituents of the body, food, digestion, absorption, blood, circulation, respiration, secretion, metabolism, animal heat, muscles, the nervous system, special senses, and reproduction. From a pedagogic standpoint the above order is most desirable, each chapter laying the foundation for the succeeding one.

Such tables as that at the end of the chapter on digestion are of pedagogic value. It is entitled "Résumé of Action of the Digestive and Liver Ferments."

The practitioner of medicine will be especially interested in the subchapter on blood devoted to "Medicolegal Tests;" also the subchapter on "Immunity" discussed from a standpoint of the physicians and giving the latest data on zymoids, antitoxins, agglutinins, precipitins, cytotoxins and opsonins.

The subchapter on internal secretions is unusually full and valuable. The author fails to mention, however, the important work of Brown-Séquard, Poehl, Zoth, Morris, Glass, Loewy and Richter showing conclusively that there is an internal secretion produced by the testes and ovaries, as well as by the thyroid, suprarenals and pituitary. The chapter on metabolism is well arranged; the author has caught the spirit of the modern notions on animal nutrition. The subchapter on animal heat is especially good. The chapters on the central nervous system, the special senses, and reproduction are well presented to give the student to get a good working knowledge of these subjects; but do not present striking characteristics.

Confidences. Talks With a Young Girl Concerning Herself. By Edith B. Lowry, M.D. Cloth. Price, 50 cents. Pp. 94. Chicago: Forbes & Co., 1910.

Beginning with the blossoming of flowers from the seed, in this book the child's mind is led to the birds, their eggs and nests, and then to the human organs and processes, for the explanation of the elementary facts about the girl's sexual life. The language is inconsistent at times; that is, part of the book is almost in "baby-talk," while other parts are scientific and contain rather long words. This is no material disadvantage, however, as the chapters are in the form of heart-to-heart talks and can be adapted by the parent to the age of the child.

The plan of the book is good in that the account of sexual matters is interwoven with the explanation of objects of nature in which the child is interested and also with hints about general hygiene. This excellent plan will guard against the possibility of the sexual facts assuming too much prominence. The wise parent can add to the general remarks, using this book for a frame-work and not telling the whole story at one time.

Part of the book is most elementary; that is, it aims at being the very first information the little girl may receive; other parts need not be presented until just before puberty, perhaps. There is no attempt at details of anatomy. The only criticism we have on the book is the absence of explanation of the male in the animal world and in the human family, although a foundation has been laid for it in the description of the work of the pollen in flowers. It is true that the male can be ignored for a time, but it will not be long before the girl will ask—of the parent if there is the proper family confidence, or else of a companion—why boys are different from girls. Then the parent would gladly turn to this book again if it offered help on this question, which may be harder to answer wisely than those which have come before. In addition, we feel that social conditions are such that a girl is not adequately safeguarded unless she understands not only herself but the male. We recommend the book.

A System of Medicine. By Many Writers. Edited by Sir Clifford Allbutt, M.D., Regius Professor of Physic in the University of Cambridge, and Humphry D. Rolleston, M.D., Senior Physician, St. George's Hospital. Vol. VII. Diseases of the Muscles, the Trophoneuroses, Diseases of the Nerves, Vertebral Column, and Spinal Cord. Cloth. Price, $6 net. Pp. 900, with 98 illustrations. New York: Macmillan Co., 1910.

In this volume are discussed the diseases of muscles, including amyotonia congenita, myasthenia gravis, family periodic paralysis and the neuritic type of progressive muscular atrophy, the trophoneuroses, diseases of the nervous system, nerves, spinal cord and meninges. The advances made in neurology during the past ten years are reflected in the section on diseases of the nervous system. The introduction to neuropathology by Mott and the article on medical ophthalmology by Gowers are new. Diseases of the cauda equina and of the sympathetic nervous system are also included here. Herpes zoster is classed as a nervous affection. Many changes and additions have been made in the articles on myelitis, paraplegia, caisson disease, Landry's paralysis, ataxia and syphilis. Chronic anterior poliomyelitis and amyotrophic lateral sclerosis are described under the caption, "Motor Neuron Disease." The neurologist will be pleased with the presentation of his special subject, because everything new up to the time of publication receives a full measure of attention. The typographic and mechanical part of the book is in keeping with that of previous volumes.

A Text-Book of Bacteriology. A Practical Treatise for Students and Practitioners of Medicine. By Philip H. Hiss, Jr., M.D., Professor of Bacteriology, College of Physicians and Surgeons, Columbia University, and Hans Zinsser, M.D., Associate Professor in Charge of Bacteriology, Leland Stanford, Jr., University, Palo Alto, Cal. Cloth. Price, $3.75. Pp. 745, with 156 illustrations. New York: D. Appleton & Co., 1910.

This book might well have the title "Medical Bacteriology," inasmuch as the subject is discussed from the medical standpoint—the actual relation of bacteriology to medicine. Only one section of about fifty pages is devoted to the bacteria in air, soil, water, and milk—non-pathogenic organisms. The remaining 660 pages are devoted to the pathogenic germs, their morphology, biology, and methods of study. Thirty pages are devoted to diseases of unknown etiology, such as rabies, small-pox, acute anterior poliomyelitis, measles, scarlet fever, yellow fever, and foot and mouth diseases which are probably of bacterial origin, but in which the germ is as yet ultramicroscopic. The book is adapted more to advanced courses in bacteriology than to introductory courses. The language used is highly technical and the discourse exceedingly technical. The student of medicine who has been properly prepared to carry on the study as outlined in the book will profit from it—but the unprepared and especially the practitioner who wishes to review the subject will find it rather difficult to use the book as a text. Nevertheless it should be recommended for what it is—an excellent medical bacteriology.

Walsh's Physicians' Combined Call-Book and Tablet. Flexible Leather, with Flap and Pocket. Price, $1.50. Washington, D. C.: Ralph Walsh, M.D., 1807 H Street N. W.

Walsh's Physicians' Handy Ledger. A Companion to Walsh's Physicians' Combined Call-Book and Tablet. Half Leather. Price, $3.50. Pp. 600. Washington, D. C.: Ralph Walsh, M.D., 1807 H Street N. W.

The Walsh system of medical bookkeeping employs a pocket call-book in the usual form used by physicians, which contains, in addition to the pages for entries, an obstetric record and cash account; an obstetric table; table of eruptive fevers; table of changes in the Pharmacopeia; dose table; table of metric equivalents: and a table of poisons and antidotes. To be used in connection with this is a ledger, each page of which, in addition to the space for the name and residence of the debtor, is arranged so that the transactions for each month are shown on a single line, the particular service being indicated under the date by a character. It also contains space for dates and amounts of payments. The books make a condensed but comprehensive system of bookkeeping for the physician, which can be commenced any month of the year.

History of the Medical Society of the District of Columbia. 1817-1909. Cloth. Price, $3. Pp. 499, with illustrations. Washington: Medical Society of District of Columbia, 1909.

This book has been prepared by a committee of the society from presidential addresses, volumes of transactions, manuscript and printed records of the society, as well as from current medical periodicals. A large number of photographs contributed by members appear throughout the book, as well as pictures of the various meeting places of the society, and other Washington buildings of historic and medical interest. Two hundred pages are devoted to a history of the society from its organization in 1817 to the present time. The rest of the book is devoted to a list of members arranged in the order of election, with a short biographical sketch of each. An appendix contains the original constitution and by-laws, together with all additions and changes, and the membership of various committees. A copious index of both persons and subjects makes the material in the volume accessible for ready reference. The book is of value not only to members of the Medical Society of the District of Columbia, but also to all interested in medical history. The society is to be congratulated on the volume which its committee has produced.

Medicolegal

Construction of Washington Medical Practice Act as to Persons Entitled to Licenses by Prior Practice—Titles to be Used—Exempting Former Illegal Practitioners—"Practice"

The Supreme Court of Washington affirms, in re Christensen and others (109 Pac. R. 1040), judgments reversing decisions of the Board of Medical Examiners and directing a license to be issued to each of the applicants, who had been for more than two years prior to March 18, 1909, the date of the approval of the law, a resident of the state, and had for the same period been in continuous practice, in one locality in the state, of his or her respective mode of treatment.

This law, the court says, purports to cover the entire subject matter of licensing practitioners of medicine and other modes of treating the sick or afflicted. It does not purport to amend any prior existing law, and expressly repeals all laws in anywise conflicting with its provisions. In section 4 it provides: "Any person who treats the sick or afflicted may register his or her diploma with the board of medical examiners, and receive a license to practice his or her respective mode of treatment, by paying a fee of $10, * * * Provided, that he or she show evidence satisfactory to said board that he or she had been legally engaged in such practice prior to the passage of this act, in the state of Washington, and is a graduate of a legally incorporated school or college * * * ; or by having been in continuous practice in one locality in this state for the past two years. * * * " Section 6, which refers to those licensed on examination, requires the applicant to file "satisfactory testimonials of good moral character, and a diploma * * * ." Section 20: "All persons receiving a certificate or license under this act shall use no deception in the use of titles of his or her mode of treating the sick, but shall use only such titles as are designated by his or her diploma; or those not having a diploma shall use only such title as he or she holds license to practice. * * * "

It was contended in behalf of the Board of Medical Examiners that an applicant must, in addition to showing two years' practice in one locality, have a diploma and register the same with the board before he would be entitled to a license under the provisions of the last clause above quoted from section 4. It must be conceded that the provisions of this law are somewhat involved, and that the question of its meaning is not free from doubt. However, the court is of the opinion that one who has been in continuous practice in one locality in the state of Washington for two years prior to the enactment of this law is not required to furnish further evidence of his qualifications by a diploma, and that such a person would be entitled to a license regardless of the fact of his ever having a diploma.

By section 20 it clearly appears that the legislature had in mind that at least some of those entitled to a license under this law should not be required to show their qualifications by diplomas. It was contended that the words "those not having a diploma" referred only to a licensee under section 6 on examination, who is required to produce a diploma from a medical school of a certain standing "or satisfactory evidence of having possessed such diploma." But the court cannot agree with that contention. It seems to the court that if a person ever had such a diploma, and is basing his right to a license on it, as he must under section 6, he will be governed in using his title as a practitioner by that which is designated in such diploma, whether he has physical possession of such diploma at that time or not. In other words, if he has or ever had a diploma, and is granted a license on it, then its designation of his title will govern, whether it has any present physical existence or not. He is not one of those mentioned in section 20 as "not having a diploma." The only licensees mentioned in this law that these words could possibly refer to are those who are entitled to licenses by virtue of practice in one locality in the state for two years as provided in section 4. It is quite common, in laws regulating professions and vocations and prescribing qualifications to be possessed by those entering on them, to exempt those already engaged in them from showing any qualifications other than the fact that such persons are already so engaged, or have been so engaged for a certain time. This seems to have been the policy pursued by the Washington territorial and state legislatures. And it has been held that such a provision is not such a discrimination as violates any constitutional right of those seeking to enter such professions or vocations.

It appeared that some of the applicants here were engaged in the practice of medicine and surgery for the two years prior to the passage of this law without having a license required by the law as then existing. This, it was contended, excluded such a person from the right to a license, because he was not legally engaged in practice and therefore was not engaged in practice at all within the meaning of the two years' practice clause of section 4. But it has been noticed that the law here involved is a new and independent act complete in itself, and repeals all former laws on the subject. That part of section 4 following the word "provided" refers to two classes who may receive licenses. The first are persons who have been "legally engaged in such practice prior to the passage of this act." The second are those persons who have been in "continuous practice" in one locality for two years. It may be difficult to see a reason for the legislature exempting one class from the effect of their unlawful acts, and not the other; but the use of the word "legally" in referring to one class, and omitting it in referring to the other, clearly indicates the legislative intent to give the license privilege to the second class, even though they have violated a previously existing license law. The offense was in any event purely statutory, merely a misdemeanor, did not involve moral turpitude, and there is nothing so extraordinary in granting the license privilege by the legislature to those engaged in practice for two years, even though such persons did thereby violate the then existing license law, as to suggest that the court should attribute to the word "practice," as here used without qualification, any other than its ordinary meaning.

In re Harold (109 Pac. R. 1043), decided at the same time that the foregoing decision was rendered, it appeared that the applicant became a resident of the state of Washington, January 1, 1909, having been prior thereto a resident of the state of Indiana and engaged in the practice of medicine and surgery therein. Since then, and until after the enactment of this law, he was engaged in the practice of medicine and surgery in the state of Washington without having a license so to do as provided by the then existing law. In addition to showing such practice in the state of Washington he presented his diploma and evidence showing graduation from a school having the curriculum specified in section 4 of the law.

It was contended in his behalf that, by his showing of graduation from a school having the required curriculum of study and his practice in the state of Washington prior to the enactment of the law, he had thereby complied with all of its requirements, relating to a certain class, entitling him to a license; while it was contended in behalf of the Board of Medical Examiners that since he was not legally engaged in the practice in the state of Washington prior to the enactment of the law he was not entitled to a license, except he prove his qualifications as required by other provisions of the law. Here the court holds that the board was right.

It is manifest, the court says, that at the time this applicant was engaged in the practice of medicine and surgery in the state of Washington from January 1, 1909, until the time of the enactment of this law without having a license so to do, he was violating the plain provisions of the then existing law regulating the licensing of physicians and surgeons. This being true, it needed no argument to demonstrate that he was not "legally engaged in such practice prior to the passage of this act." The court finds nothing in the law warranting its giving to the word "legally" any other than its ordinary meaning. In the decision in re Christensen and others the court recognized that the legislature acted advisedly in using the word "legally" in this clause and omitting it from the two-years' practice clause. The court concludes that within the meaning of the law this applicant was not engaged in such practice prior to the enactment of the law as would aid him in procuring a license thereunder.

8 Pelvic Peritonitis Complicated by Postoperative Hysteria. J. D. Whitall, Philadelphia.
9 Hepatic Syphilis. M. Goldsmith, Pittsburg.

5. **Acute Primary Polymyositis.**—The occurrence of a primary polymyositis or an inflammation of the muscular tissue in general, says Clowe, has been disputed by many observers. By a certain number also the condition has been held to be always a local one. Recently, however, a number of cases have been placed on record, and the clinical picture is so definite a one that there seems to be no room for doubt that the disease may be accepted as a clinical entity. The picture is a clear cut one. A woman, aged 28, family and personal history unimportant, quite of her usual strength, complained of constant pain and weakness in her arms and shoulders. There was a pronounced wrist-drop. By Thanksgiving her trouble had increased and she showed signs of considerable trouble in her legs. After a careful examination made at this time the diagnosis was made. By December 10 the patient could not walk and had marked pain and soreness in all the muscles of the legs and arms. Those most affected were the biceps, flexors of the hand and wrist, the calf muscles and the thigh. The muscles were hard and of a peculiar rubbery feeling. There was at this time no rise in temperature; electric reactions and normal reflexes were present but weak. Appetite was good, bowels were regular but moved with difficulty on account of weakness, needing to be assisted by an enema. Patient slept well but was much annoyed by not being able to turn herself in bed or adjust the bedding. Also was much tired by the effort of holding up her head and trunk.

During January and February the patient improved gradually. Strength returned slowly but contracture became marked. If the hand was extended on the wrist the fingers were greatly flexed and if the fingers were extended the wrist was flexed. The same condition prevailed in the legs. She could only walk by wearing very high heeled shoes. If her shoes were removed, on standing she could not get her heels on the floor. Examination at various times showed a normal blood-count; no eosinophilia; no bacteriemia at any time; urine normal. During the stage of great weakness she suffered from hyperidrosis. In March and April improvement was more marked; contractions were much lessened. She could walk and use her hands fairly well to sew and feed herself; could comb her hair. There was still more weakness of the extensors than of the flexors; some of the muscles were markedly atrophied. The patient had gained about 10 pounds in weight.

17 *Transmission of Bacteria by Flies with Special Relation to an Epidemic of Bacillary Dysentery. S. T. Orton and W. L. Dodd, Boston.
18 *Brown Séquard's Epilepsy in the Guinea-Pig. A. E. Taft, Palmer, Mass.

17. **Transmission of Bacteria by Flies.**—An organism conforming to the Shiga type of *B. dysenteriæ* was recovered from ten out of fifteen cases examined by Orton and Dodd.

B. prodigiosus planted in the laundry was recovered from flies caught in traps in the scullery and five screened ward dining rooms at an interval of from two to six days after the original plant.

It proves impracticable in most insane hospitals to keep the flies from access to fecal matter and from food when they are present outside in large numbers and, therefore, the best prophylaxis against fly-borne epidemics is in cleaning up the breeding places of the fly to reduce its numbers or eradicate it.

The typhoid fly—*Musca domestica*—breeds in tremendous numbers in decaying vegetable waste of varying sorts, and a search for maggot-infested places with subsequent attention thereto offers the best line of attack.

The house fly's egg to adult cycle is ten days, so that vegetable waste should be cared for at least once a week during fly season.

Horse manure may be treated by chemical means, but it is probable that, if it is kept dry and in the dark, but little breeding will take place. Mixing with many times its bulk of cow manure may prove effective. The authors urge that when possible, all waste material should be ploughed into the land without accumulating. Spreading over the land will probably suffice to reduce the pest markedly.

In hospitals surrounded by considerable ground it is probable that the great majority of flies are home grown, and the extermination of their breeding places is an object which cannot be overlooked.

18. **Epilepsy in the Guinea Pig.**—The work of this report was undertaken by Taft to observe more particularly the transmission from parent to offspring of the "epileptic" and associated conditions. It has been continued during a period of eighteen months, and is based on observations made on 195 animals. Of this number, 68 were subjected to a lesion of the sciatic nerve. The remainder were the normal animals used, and the succeeding generations.

Taft found that lesions occurring in the cord or principal nerve trunks of guinea pigs produce a tendency to convulsions resembling epilepsy in the human subject. The attacks, however, have not been proved spontaneous, but may be elicited by irritation of a specific zone of skin on the side of the face and neck corresponding to the injured nerve. In this series 97 per cent. of the animals in which the sciatic nerve was resected developed convulsions; the remainder, 3 per cent., showed only the scratch reflex. The scratch reflex, the first manifestation of the nervous lesion, developed at the end of a period averaging eighteen days after the division of the nerve. The complete convulsion appeared on an average of one month and nine days following the injury to the nerve and eighteen days after the development of the scratch reflex. Age proved not to be an absolute factor in relation to the time of development of the convulsions.

The zone of irritation varies in extent. The sensitive area is at first limited to the skin over the side of the face. This extends progressively with the further development of the convulsive tendency to include the shoulder and often some distance beyond the border of the scapula. The degree of sensitiveness varies in individual cases. Sometimes merely touching the hair will produce an attack, while in others definite moulding of the skin is required. Trophic changes occur in the zone of irritation, manifested often by falling of the hair, leaving the skin exposed; or it may be the hair becomes brittle and breaks off, thus causing a roughening of the coat. In extreme cases the skin may ulcerate. As a rule, parasites accumulate over the area and there is some anesthesia. The convulsion follows irritation of the sensitive zone and is preceded by the scratch reflex. Following this, the animal falls on its back with eyes closed, insensible, and all its muscles in a state of tonic, followed by clonic, convulsion. The attack is usually brief, but may be spontaneously repeated several times. For some time following the return of consciousness the animal is somewhat stupid and dazed. It was found that the animals would in most cases respond to repeated irritation, though some could be made to react only once without an interval of some hours to a day or more. Severity of attacks depended on the size and physical condition mainly, though no rule could be applied to all cases. Those developing the attack most quickly were subject to the most severe convulsions. The effect of convulsions was productive of a marked loss of flesh, and this bore no relation to the quantity or quality of food given. Lessened reproduction was also universal, and in almost every instance of birth of young they were not alive or died immediately after birth. This was proved not to be due directly to the division of the nerve, for by limiting attacks to not more than one each week, perfectly normal offsprings were born. This would seem to show a marked disturbance in metabolism due to frequent convulsions. The study of 128 offspring of epileptic animals to observe the transmission of epilepsy, reported by Brown-Séquard to have been seen in his series, was absolutely negative. Four young were very weak at birth and died on the second day, but showed no other symptoms. The fact that convulsions in the offspring of epileptic animals always, in Brown-Séquard's experience, existed with a lack of toes, makes it seem possible that there may have been some prenatal injury which would produce the same effect as a division of the nerve. The thirteen young of the second and third generations were also negative.

36 *Case of Recurring Abscesses of the Liver. R. Brooks, U. S. Army.
37 Rabies. E. R. Whitmore, Manila.

34. **Production of Immune Bodies.**—According to the results obtained by others and those reported by Ruediger, it seems that animals that do not react after inoculation with cattle-plague blood may produce serum which in immunizing value is equal to, or nearly equal to, serum obtained from animals in which inoculation with cattle plague blood is followed by a good reaction.

36. **Recurring Abscesses of the Liver.**—In March, 1906, an abscess of the liver developed in Brooks' case, which ruptured into the pleural cavity. This was drained through an incision made by resecting a portion of the sixth rib in the right axilla. According to the patient's statement, the pus was of a red color and of a viscid consistency. At the end of three months he was returned to duty and remained well for some time. In October, 1909, the patient was admitted to the hospital again with fever, hepatic tenderness and enlargement of the liver. A diagnosis of liver abscess was made and the pus drained by resecting a portion of the seventh rib in the posterior axillary line. A large quantity of reddish glutinous pus was evacuated, which was not examined microscopically. After a tardy but uneventful recovery he was returned to duty in March, 1910. August, 1910, he was admitted to the hospital with a temperature of 100 F. and a swelling about the size of a lemon in the epigastric region, which moved up and down during respiration. Liver abscess was again recognized and the pus liberated through a median incision. At the time of the operation the liver was adherent to the parietal peritoneum and an abscess of the left lobe was found. The pus presented the same qualities as on the former occasions. On microscopic examination no amebas were found and no growths were obtained on the ordinary culture media. The recurring abscesses in this case are explained by Brooks by assuming that man may become a dysentery carrier for a number of years without any clinical manifestations of intestinal disease, or what appears to be more rational, by assuming that the parasites are capable of remaining latent in one or more hidden foci of infection, and from time to time resuming a pathogenic action.

45 Fibroid Tumors of the Uterus. Their Treatment. J. H. Carter, Memphis.
46 Iritis. R. Fagin, Memphis.

43. **Pernicious Malaria.**—As a prophylactic measure against the recurrence of fever, not by a reinfection but because the quinin did not destroy all the parasites, and by rapid multiplication gain sufficient force in a week or ten days to produce a fever, Sutherland pins his faith more on the daily use of quinin than on any other measures, and he thinks 2 grains, three times a day, is sufficient. A prescription which he has used for many years, is:

℞		gm. or c.c.
Quinin sulphate	ʒ 2	8
Aromatic sulphuric acid	℥ 1	30
Tincture chlorid of iron	ʒ 4	16
Water q. s.	℥ 8	240

S. Teaspoonful in water three times a day.

He would not recommend to a person who had not had malaria the daily use of quinin as a prophylactic measure, unless it be to one who was making a visit of a week or two into a malarious section.

63. **Strangulated Hernia.**—The patient was a male infant, aged 14 months, who had suffered from a left-sided inguinal hernia since birth. Strangulation had been present for thirty-six hours, and after an unsuccessful attempt to reduce it, with the patient under chloroform, Williams decided to operate. On opening up the inguinal canal and the sac, the contents were found to be cecum and appendix, which latter measured 3 inches in length. After the removal of the appendix and replacement of the intestine into the abdominal cavity the congenital sac was obliterated by a continuous catgut suture and an operation for radical cure was performed. The patient made an uneventful recovery, and did not seem to suffer any inconvenience from the operation at any time.

69 *Case of "Wandering" or Parasitic Fibrocystic Tumor of the Uterus. I. S. Stone, Washington, D. C.

69. **Wandering Tumor of the Uterus.**—In this case a diagnosis of ovarian tumor was made and operation done. After the trocar had evacuated more than a quart of fluid, a growth was discovered, the posterior portion of which was solid or semi-solid; no adhesions or pedicle nor any attachment to either uterus or ovary. Comparatively slight pressure on the flanks caused the sudden expulsion of the tumor. The only place of attachment found was a point near the right parovarium, or between the ovary and fimbriated extremity of the tube. This attachment did not contain large vessels such as are seen in pedicles, and needed neither ligature nor suture; the raw surfaces were closed with fine sutures, as usually done

for the prevention of adhesions The recovery of the patient was prompt and uneventful Stone is of the opinion that this tumor was one of parasitic or migratory character, having its origin within the muscular wall of the uterus Its solid portion was precisely similar to the typical uterine fibromyoma, and its microscopic examination confirmed this observation The tumor had separated from its uterine attachment by torsion of its pedicle and strangulation of its vascular supply, which ultimately resulted in atrophy of the pedicle and its complete absorption.

73 *Rationale of Transverse Abdominal Incisions S S Hesselgrave, St Paul
74 Pathology and Treatment of Puerperal Infection J L Rothrock, St Paul
75 Bovine Tuberculosis as a Public Welfare Problem M H Reynolds, St Paul

73 **Transverse Abdominal Incisions**—Hesselgrave claims to get much better results since he began using the transverse incision and since the only important change he has made in the technic is the direction of the incision, he thinks it only fair to ascribe the improvement to the direction of the incision The vertical incision is poorly supplied with arteries and veins to feed the wound and carry away the debris, and when the recti muscles are forcibly retracted for some time the bruising of the wound margin is a factor in wound reaction and the cause of the "soreness" always complained of after an operation done by this method The absence of this complaint and the ability of patients to move themselves about unaided directly after the operation are noticeable features of the transverse incision

The most important advantages of the transverse incision to the operator are 1 Easier and less tiring operating on account of the direct access to the field of operation and the better view of the area involved 2 Simplicity, one does not have to learn a multitude of incisions running every which way It is only necessary to learn the anatomy of the cross section of the abdominal wall above and below the semilunar fold of Douglas and to make an effort to keep the incision within the limits of the semilunar lines 3 One is never embarrassed for want of space, for if more room is needed than originally thought it can be obtained by extending the incision in one direction or the other, or, if need be, in both directions

Some of the most important advantages to the patient are 1 Better looking scar 2 Stronger union of the aponeuroses 3 Less pain This is especially noticeable when the recti muscles are cut, and is due to the absence of spasm of the recti 4 Less wound reaction This is due to the fact that the wound margins are not contused by retractors, and to the technic of closing the skin into which no needle nor thread penetrates 5 Less anesthetic is needed, particularly when the recti muscles are cut, because we have no rigidity to overcome 6 Greater protection is offered the intestines, which are retained within the cavity surrounded by their normal envelope 7 Less gauze packing is necessary and we should never hear of a yard piece being left in the abdomen since they are all within reach of the eye 8 In cases of pendulous abdomen a long lozenge shaped incision will do away with the skin and fat in this deformity as a preliminary to the proposed operation 9 Shaving off the pubic hair is not necessary and everyone who has been subjected to this measure has been grateful for its discontinuance

79 **Cancer Residue**—The attempt has been made by Vaughan to find proof with regard to the formation of a specific ferment by the injection of the non toxic proteid of the cancer cell, through a study of the various blood elements, particularly the leukocytes, and some interesting findings have been recorded The cases on which he made his observations, all belong to the inoperable group, cases of uterine, ovarian and breast carcinoma From a study of the cases cited, and their blood findings, certain definite conclusions can be drawn Especially is this true since the clinical course of the disease seems to progress either favorably or unfavorably in direct ratio to the changes in percentage of the white blood cells that injections of cancer residue produce Thus, if the percentage of mononuclear cells increases markedly following a residue injection, a more favorable prognosis can be given than if no such reaction is obtained Many cases in which to the examining eye it appears that all cancer cells can be removed, are in reality inoperable cases, and evidence of this truth is only too frequently shown after operative treatment has been applied Such cases, however, are regarded by Vaughan as the ideal ones in which to apply the use of cancer residue, since the number of cancer cells remaining in the host after removal of the tumor is sufficiently small so that their total destruction should be assured

During four and one half years of trial there has not been a known recurrence in cases belonging to this group With inoperable cancer, to which group all cases reported here belong, the amount of cancer tissue may be so large that a too rapid splitting up of the malignant cells may be a menace to the patient Vaughan has had several cases which, after prolonged treatment and large injections, have shown gastrointestinal disturbances such as diarrhea and vomiting, together with rapid pulse rate and slightly subnormal temperature However, since a study of his cases and others shows that large doses do not cause the tumor cells to disappear with the rapidity that small injections do, Vaughan is more prone to attribute these untoward symptoms to the size of the injection Nevertheless, since every proteid contains a toxic group, it can easily be imagined that too rapid destruction of a large amount of cancer tissue would be of danger to the patient For this reason, in many instances, he has removed as much malignant tissue as possible before beginning residue treatment In every case that this has been done, the skin incision has healed by primary union, regardless of whether cancer tissue was macroscopically left or not, consequently Vaughan can see no logical reason why such a procedure should not be adopted

He impresses the following facts 1 The injections should always be small in amount, preferably 5 to 10 minims of a ½ to 1 per cent solution 2 Injections, according to present knowledge, should be controlled by daily differential leukocyte counts 3 Injections should be made only when the percentage of mononuclear cells is on the decrease 4 A good blood reaction, by which is meant an increase of from 10 per cent up of mononuclear cells following residue injection tends toward a favorable prognosis 5 If the blood count does not respond, smaller doses should first be tried, if this fails to produce the desired change, different residues should be used until one is found which brings about this result

94 *A Neurodermatologic Case. H. E. Menage, New Orleans.
95 Intracapsular Fracture of the Femur. U. Maes, New Orleans.
96 Ciliary Muscle and Accommodation. T. J. Dimitry, New Orleans.

94. **Neurodermatologic Case.**—A critical analysis of this most interesting case forces Menage to place it in the category of the so-called hysterical gangrene, spontaneous gangrene of the skin, disseminated gangrene of the skin, and dermatitis factitia or artefacta. The diagnosis he made is hysterical gangrene, but of self-inflicted type, as differentiated from the spontaneous class. When first seen the patient, aged 19, presented ulcers on the lower lids and lesions of the conjunctivæ, which apparently had resisted, in a great measure, all lines of treatment. The lesions would improve, almost get well, then suddenly, without known cause, become as bad as ever, if not worse. A tentative diagnosis of tuberculosis of the lids was suggested, but subsequently proved incorrect by the negative tuberculin test applied. As subsequently observed, the ulcers proved to be the result of spontaneous circumscribed and discrete gangrenous patches; the process being complete in an incredibly short space of time. The first crop of the lesions made its appearance about November of last year, above and below the right knee. When Menage saw them, about twenty-four hours after their appearance, they consisted of large, deeply-seated, irregularly-shaped areas of coal-black, hard, gangrenous skin, surrounded by little or no inflammation. The outline, although irregular, was clean-cut and appeared to have been stamped. There were no especial subjective symptoms, no febrile reaction, and no general disturbances of any kind. The patches measured in size, irregularly, from a split pea, to one two and one-half by two inches. In the course of time the sloughs separated, leaving clean, deep-seated, granulating ulcers, which appeared quite healthy. Within a short time, probably two weeks, after the first series, another appeared on the left leg; in about the same relative location and having the same characteristics, except in configuration. From that time to this date the patient has been under observation, more or less constantly, and new lesions have been seen to develop on almost all accessible parts of the body; none, however, quite as severe as in the first and second outbreaks. Menage is not able to say how and with what the patient causes these lesions, or whether the injury is caused with premeditation or unconsciously during a period of somnambulistic or subconscious personality.

118 *Treatment of Acne Vulgaris with Acne-Bacillus Suspensions. M. F. Engman, St. Louis.

115. **Carl Spengler's "I. K."**—Benker has used Carl Spengler's "I. K." (Immune Bodies) in eight cases. One patient improved considerably in the subjective state, the lung process slightly improving and the tubercle bacilli disappearing from the sputum. In case 2, the subjective state was aggravated as well as the lung process. The temperature increased from 100 to 102 F. The sputum showed no change either in appearance or quantity of bacterial contents. The six patients in stage III died. The lung process grew progressively worse. The sputum did not show the slightest changes, though three cases were ameliorated in the subjective state.

118. **Acne Vulgaris.**—The treatment of acne vulgaris with suspensions of acne bacillus has proved, in Engman's hands, since a proper technic has been adopted, the most brilliant therapeutic agent yet seen in dermatology. Some of the cases respond as does the membrane in diphtheria to its antitoxin; nothing else in medicine can compare with its action in favorable cases. There is only one drawback in these very favorable cases and that is the lesions undergo such complete and rapid involution that deeper and more marked scars supervene. Nothing demonstrates Wright's negative phase better than these suspensions in acne. Invariably two or more new lesions appear within forty-eight hours after the injection. If a large dose is given, a numerous crop can be produced, and the negative phase prolonged for days. By repeated large doses, a mild case can be aggravated or converted into a severe one with large cystic lesions; and, furthermore, the positive phase in such instances is not clinically evident. Such a patient remains for some time extremely sensitive to any dosage. Such has been Engman's experience with doses of 50,000,000 at seven-day intervals, an experience repeated several times by him. Mild cases stand a larger dose than severe ones; in the latter, continuous small doses give the best results.

8 **Influence of Sour Milk on Metabolism**—The conclusions drawn by Harley from analyses on metabolism when a small quantity of sour milk is given in addition to the ordinary mixed diet can be placed under two heads First, the influence on increased intestinal putrefaction The quantity of the aromatic sulphates is seen to be decreased, although this is not in any considerable quantity, but in none of the cases were the aromatic sulphates very large to commence with The increased indican in the urine also appeared to be somewhat decreased in quantity In all the cases the stools became much less offensive in odor when a small quantity of sour milk had been added to the diet The results of Schmidt's fermentation test further indicated a decrease in the intestinal putrefaction, and the marked alkaline condition of the stools tended to become either neutral or even acid The chemical analyses gave indications that there was a decrease in the intestinal putrefaction Secondly, the influence on the absorption of food The quantity of nitrogen in the stools is certainly increased by the addition of sour milk to the diet, and this increase in the quantity of nitrogen present causes the apparent decrease in the absorption of nitrogen by the bowel It must be here remembered that the nitrogen contained in the stools is not really the nitrogen in the food, which remains undigested, but is the nitrogen contained in the various secretions that are eliminated into the bowel, together with mucus, epithelial cells, and the remains of numerous bacteria in the intestine, so that although the nitrogen absorption may apparently be decreased, there is in all probability no real decrease in the absorption of nitrogen The fat, however, in the stools, appeared to be slightly increased in quantity in two cases The analytic results of the absorption of the food after the addition of small quantities of sour milk to an ordinary diet do not apparently point to any better absorption of food

9. **Chrysarobin**—Unna proposes a generous use of chrysarobin siccatifs and of ointments containing besides chrysarobin, oleates of lead After a year's experience, he recommends this form of treatment of psoriasis as an especially quick and thorough one

11 **Treatment of Morphinomania.**—The details of the treatment which Miller recommends are as follows: 1 A course of nine weeks in a nursing home or similar institution. He considers this period as long as desirable and yet short enough to bring the cure within the reach of most patients 2 Examine the patient and make sure there is nothing to contraindicate the treatment 3 Explain to the patient very fully the nature of the cure Let him see that you do not mean to treat him as a criminal, but that you want to help him Explain that you will allow him practically as much morphin as he asks for during the first three days, and that by the end of that time he will be sound asleep, and free of the craving 4 During the first three days of treatment, the patient should get a diminishing number of injections of diminishing strength and on the third day the injections should be per rectum 5 Before each injection he has to take a draught containing 5 grams of sodium bromid The total for the three days should work out at about 100 grams By the end of the third day both bromid and morphin are stopped, and the patient will be in a comatose or semicomatose condition which will last for three to six days more 6 During all this time the patient is roused to take milk at regular intervals, and to be placed on the commode to empty bowel and bladder 7 When the effects of the bromid begin to pass off there will be in all probability a certain amount of mental confusion, including hallucinations, delusions of persecution and so on These will pass off soon 8 As soon as the patient appears to be sufficiently sensible efforts should be made to hypnotize him, and the lethargic state he is in will materially assist Suitable suggestions must be made without waste of time lest the craving should reassert itself before the mind is sufficiently influenced This is the critical point of the whole cure 9 As soon as possible the patients should be brought into one room and hypnotized collectively This Miller considers of very great importance, as would any one who has seen the method practiced abroad All the most successful exponents of treatment by suggestion on the Continent lay great stress on the value of this method —Bertillon, Van Renterghem, the late Dr Wetterstrand, and many others It serves two purposes: (a) to facilitate the hypnotization of obstinate patients, (b) to enhance the effect on all that respond 10 During this period, that is, from the second to the end of the seventh week, the patients should be strictly supervised and no access to drugs allowed Everything is done to make life interesting, and to promote the general health of the patient 11 During the eighth and ninth weeks the patients should be allowed to keep their morphin and syringes The hypnotic sittings should be reduced in number, and should have special reference toward teaching the patient to put himself to sleep, that is, autohypnosis Autohypnosis is, says Miller, a mental knack or trick that can be acquired through hypnotic suggestion by all but a certain percentage of mental invertebrates Once acquired, this power will serve to give the patient in the future a ready refuge from worry or pain, or anything else that might lead to thoughts of morphin

17 **Treatment of Lobar Pneumonia**—The central fact in this paper is the employment of a certain drug combination in twenty cases of lobar pneumonia with no mortality, but with abortion of four of the cases The treatment advocated is the administration from the time of diagnosis of a combination of creosote and potassium iodid Mathison gives, from the time of diagnosis the following prescription, and to minors one of strength proportionate to their age Potassium iodid, 1 dram, creosote, ½ dram, rectified spirit, 2 drams, liquid extract of liquorice 3 drams or 4 drams of the older Pharmacopeia preparation Water to 6 ounces A tablespoonful to be taken every four hours In this combination the antiseptic action of creosote limits the extension of the pneumonic process It directly opposes the invaders, probably by making the circulation an unsuitable haunt for them, and perhaps also by digesting enzymes The iodid stimulating cell action, loosens the exudate The fluxion is diminished by the quieting effect both drugs have on the heart, by their

94 *A Neurodermatologic Case H. E. Menage, New Orleans
95 Intracapsular Fracture of the Femur U. Maes, New Orleans
96 Ciliary Muscle and Accommodation T. J. Dimitry, New Orleans

94 **Neurodermatologic Case.**—A critical analysis of this most interesting case forces Menage to place it in the category of the so called hysterical gangrene, spontaneous gangrene of the skin, disseminated gangrene of the skin, and dermatitis factitia or artefacta. The diagnosis he made is hysterical gangrene but of self inflicted type, as differentiated from the spontaneous class. When first seen the patient, aged 19, presented ulcers on the lower lids and lesions of the conjunctivæ, which apparently had resisted, in a great measure, all lines of treatment. The lesions would improve, almost get well, then suddenly, without known cause, become as bad as ever, if not worse. A tentative diagnosis of tuberculosis of the lids was suggested, but subsequently proved incorrect by the negative tuberculin test applied. As subsequently observed, the ulcers proved to be the result of spontaneous circumscribed and discrete gangrenous patches; the process being complete in an incredibly short space of time. The first crop of the lesions made its appearance about November of last year, above and below the right knee. When Menage saw them, about twenty four hours after their appearance, they consisted of large, deeply seated, irregularly shaped areas of coal-black, hard, gangrenous skin, surrounded by little or no inflammation. The outline, although irregular, was clean-cut and appeared to have been stamped. There were no especial subjective symptoms, no febrile reaction, and no general disturbances of any kind. The patches measured in size, irregularly, from a split pea, to one two and one-half by two inches. In the course of time the sloughs separated, leaving clean, deep seated, granulating ulcers, which appeared quite healthy. Within a short time, probably two weeks, after the first series, another appeared on the left leg in about the same relative location and having the same characteristics, except in configuration. From that time to this date the patient has been under observation, more or less constantly, and new lesions have been seen to develop on almost all accessible parts of the body; none, however, quite as severe as in the first and second outbreaks. Menage is not able to say how and with what the patient causes these lesions, or whether the injury is caused with premeditation or unconsciously during a period of somnambulistic or subconscious personality.

118 *Treatment of Acne Vulgaris with Acne-Bacillus Suspensions M. F. Engman, St Louis

115 **Carl Spengler's "I. K."**—Benker has used Carl Spengler's "I. K." (Immune Bodies) in eight cases. One patient improved considerably in the subjective state, the lung process slightly improving and the tubercle bacilli disappearing from the sputum. In case 2, the subjective state was aggravated as well as the lung process. The temperature increased from 100 to 102 F. The sputum showed no change either in appearance or quantity of bacterial contents. The six patients in stage III died. The lung process grew progressively worse. The sputum did not show the slightest changes, though three cases were ameliorated in the subjective state.

118 **Acne Vulgaris.**—The treatment of acne vulgaris with suspensions of acne bacillus has proved, in Engman's hands, since a proper technic has been adopted, the most brilliant therapeutic agent yet seen in dermatology. Some of the cases respond as does the membrane in diphtheria to its antitoxin: nothing else in medicine can compare with its action in favorable cases. There is only one drawback in these very favorable cases and that is the lesions undergo such complete and rapid involution that deeper and more marked scars supervene. Nothing demonstrates Wright's negative phase better than these suspensions in acne. Invariably two or more new lesions appear within forty-eight hours after the injection. If a large dose is given, a numerous crop can be produced, and the negative phase prolonged for days. By repeated large doses, a mild case can be aggravated or converted into a severe one with large cystic lesions; and, furthermore, the positive phase in such instances is not clinically evident. Such a patient remains for some time extremely sensitive to any dosage. Such has been Engman's experience with doses of 50,000,000 at seven day intervals, an experience repeated several times by him. Mild cases stand a larger dose than severe ones; in the latter, continuous small doses give the best results.

21 *Syphilitic Reinfection. H. FitzGibbon.
22 Sterilization of Certain Degenerates. R. R. Rentoul.
23 Catalogue of the Library of the Royal College of Surgeons of England. V. G. Plarr.

21. **Syphilitic Reinfection.**—The patient whose case is cited by FitzGibbon received syphilitic infection in June or July, 1906, which was followed by the development of complete syphilis early in August that year. He recovered under treatment by intramuscular injection of mercurial cream within twelve months. There was an interval of perfect health from any symptoms from syphilis from April, 1907, until October, 1909, during which time no treatment was undergone. About this time he exposed himself to the risk of infection, which was followed by a characteristic chancre, and the subsequent sequelæ usual in recently acquired syphilis, such as inguinal adenitis, sore throat, etc., which left no doubt of the case being one of reinfection of syphilis which must have taken place in the end of October, 1909, about the time that the patient admitted the exposure to have taken place. The dates of the respective infections were approximately July, 1906, and October, 1909, leaving only an interval of three years and three months between the first infection and the date of the reinfection. The possibility of a second syphilitic infection taking place in a person who has previously contracted syphilis and recovered from it has long since been proved beyond question by the number of cases which have been recorded on reliable authority, but the interval between the first and second infections has always exceeded five years. FitzGibbon regards his case, therefore, as quite exceptional in view of the shortness of the interval which intervened between the first attack of complete syphilis and the second infection.

24 Data and Tests in the Study of the Exceptional Child. M. P. E. Groszmann.
25 Auricular and Peri-Auricular Dermoids, Fistulas and Tumors of Congenital Origin. J. H. Evans.
26 *A Case of Lymphosarcoma. G. F. Vincent.

26. **Lymphosarcoma.**—Vincent first saw this patient, a boy, aged 9 years, on July 9. His mother noticed on the night previous while giving him his bath that his abdomen was enlarged; that he had vomited once or twice, and that the bowels had acted three times that day. She said that two or three weeks before this some friends had remarked to her that he was not looking well and seemed paler and somewhat thinner, but she had not noticed it herself. When Vincent saw him the temperature was 97 F. and the pulse 100. The stomach appeared to be distended and the costal arches were pushed forward. A considerable amount of free fluid could be detected in the abdomen, and percussion did not give rise to any pain. On July 10, his temperature was 97 F. and pulse 104, and the distention of epigastric and hypogastric regions was more pronounced. He complained of a slight pain occasionally in the right hypochondrium and had some difficulty in micturition. He vomited once and the bowels acted three or four times during the night. He measured over the epigastrium 26 inches, over the umbilicus 23½ inches, and from the xyphoid cartilage to the umbilicus 6½ inches. On July 11, temperature was 97 F. and pulse 108. He did not complain of any pain, but lay in bed reading. An incision was made in the mid-line, when about 4 pints of clear fluid came away. On inserting the finger Vincent felt a large swelling about 3 by 2 inches attached to the anti-mesenteric border of the hepatic flexure, with several swellings the size of a marble dotted over the intestine above and below this; also a swelling the size of a hen's egg surrounding the gall-bladder. Through the incision he pulled out the growth with a portion of the intestine, but in doing so it broke, for it was very brittle, although its walls appeared to be about ½ inch thick. As the gall-bladder and a large part of the intestine were involved, Vincent decided not to proceed further with the operation. He was also suffering considerably from shock, and vomited about half a teacupful of coffee grounds. Vincent replaced the swelling, put in a large drainage tube, and sent him back to bed. He died in thirty-six hours. The necropsy showed the growths on the intestine and gall-bladder mentioned, also large nodules on the lesser curvature of stomach and duodenum.

October 15, XXVIII, No. 20, pp. 1825-1920

27 *Hydronephrosis with Horseshoe Kidney. (Sur trois nouveaux cas de rein en fer à cheval.) E. Papin and E. Christian.
28 *Cancer of the Prostate. H. Young (Baltimore).

27. **Horseshoe Kidney.**—Papin and Christian report three additional cases, with hydronephrosis in two of them. They have also found nine operative cases on record of hydronephrosis with horseshoe kidney with operative treatment and fifteen cases in which the trouble was first noted at necropsy. Bilateral hydronephrosis in a horseshoe kidney has never been encountered during life. The heminephrectomy in the nine operative cases was successful in all but one; in this the fact that the kidney was of the horseshoe type was not recognized until the attempt had been made to remove the whole kidney mass. Fatal hemorrhage followed from laceration of a large vessel. Albarran did a ureteropyeloneostomy with successful outcome in one of the cases, establishing the possibility and advantages of more conservative measures than the usual heminephrectomy.

October, IV, No. 10, pp. 561-624

29 *Hypersecretion in Fasting Stomach in Relation to Ulcer. W. Oettinger.
30 The Psychic Gastric Secretion in a Gastrostomized Patient. R. Hertz and S. Sterling.

29. **Hypersecretion in Fasting Stomach.**—Oettinger regards pure gastric hypersecretion in the fasting stomach as a sign of disturbance both in the secretory and motor functioning, and says that in at least 72 per cent. of the cases it is the result of an ulcer or ulceration in the stomach. If besides the hypersecretion there is also stagnation of stomach content, the conditions favor autodigestion of the stomach wall. Among seventy-five patients with more or less gastric juice in the fasting stomach, he found fifty-four with "occult" blood in the stool. The hyperacid conditions in the stomach are liable to entail secondarily spasmodic contraction of the pylorus, or gastroptosis or the effect of corsets may aid in the vicious circle. Even in all the twenty-one cases in which the stools were free from blood, there was a history of more or less gastric discomfort, loss of weight, etc., or actual pain.

Archives de Médecine des Enfants, Paris

November, XIII, No. 11, pp. 801-880

31 *Pathology of the Thymus. A. B. Marfan.
32 *Glioma of Base of Brain. A. Hallpré.

31. **Pathology of the Thymus.**—Marfan concludes from his research that some chronic infection or intoxication is generally responsible for simple hyperplasia of the thymus. Syphilis and tuberculosis are the principal factors, and tentative antisyphilitic treatment may prove successful even in the absence of a known history of syphilis. If no benefit is derived from it, general treatment for glandular enlargement should be instituted. Injection of adrenalin, 2 to 4 drops a day of the 1 per thousand solution, seems to have a favorable action on hyperplasia of lymphoid tissue in general, and Marfan suggests its use in case of hypertrophy of the thymus. With threatening symptoms from compression of the air passages, radiotherapy, thymectomy or intubation may be considered. If there is no immediate urgency, radiotherapy might be given a fair trial. Friedländer has reported entire subsidence in an eight weeks' babe of severe respiratory disturbances under twelve Roentgen-ray exposures in thirty days, and Myers has reported similar success in another case, although he had to make forty-seven exposures in the course of three months to realize this result. In emergencies, intubation with a long tube reaching nearly to the bifurcation may

relieve the little patient of all disturbances. Inhalation of oxygen, injections of camphorated oil and artificial respiration may also prove useful. Thymectomy, however, is a relatively simple operation and is indicated in all cases of intense and lasting compression. A number of successful cases are on record.

32. **Glioma at Base of Brain.**—The special feature of Halipré's case was that the functioning of the third pair was not interfered with by the large, soft, three-lobed glioma in the base of the brain, involving the internal capsule. The optic nerves embedded in the tumor were completely destroyed, but the right third nerve, although traversing the tumor, was apparently intact and no symptoms had been observed from it. The patient was a girl of 11; the first symptoms of the tumor had been observed four years before death. They consisted at first mainly in convulsions and hemiparesis, all improving under bromids.

40 *Spontaneous Delivery with Rachitic Contracted Pelvis. M. Marioton.

40. **Spontaneous Delivery with Contracted Pelvis.**—Marioton reviews the experiences in this line at the Clinique Tarnier at Paris, in charge of Bar, with 180 cases during the last two years, striving to determine the probabilities for delivery without assistance in the various grades of rachitic contracted pelvis. This anomaly seems to have grown less and less frequent during the last half century, not only at this clinic, but according to the reports from six other maternities of Paris. The maternal mortality was as low for the women with contracted pelvis—when delivery was spontaneously terminated—as for women with normal pelves. The mortality was only 0.6 per cent., while the general obstetric mortality is now estimated at 0.5 per cent. The statistics from various clinics and the management of the cases are tabulated for comparison. The data show that with a minimum conjugate diameter (*diamètre promonto-pubien minimum*, estimated by subtracting 1.5 cm. from the diagonal conjugate), of over 9 cm., delivery is spontaneously completed in 80 per cent. of all cases; below 8 cm. this rarely occurs—not in over 25 per cent. Between these limits of 8 and 9 cm. (3⅜ and 3⅝ inches) is the debatable ground. The dividing line seems to lie between 8.5 and 8.6 up to 8.9 cm. Below 8.5, assistance is generally necessary in more than 50 per cent. of the cases. The statistics cited show that spontaneous delivery occurs 10 to 11 per cent. more frequently in women who have already borne children. With pelves over 8.6 cm., the fetal mortality scarcely surpassed that with normal pelves, being about 9 per cent., while with pelves of less than 8 cm. fully 30 per cent. of the fetuses succumbed. The influence of preceding births did not seem to affect the fetal mortality, but infants weighing not much over 5 pounds died in a proportion ranging from 22.85 to 80 per cent., irrespective of the degree of contraction of the pelvis. With infants weighing from 5 to 6 pounds and a trifle over, the mortality was from 6 to 8 per cent., increasing to 20 per cent. with pelves between 8.1 and 8.5 cm. Under 5 and 6 pounds, with a conjugate diameter of 8 cm., the mortality is a little less than for the heavier children, but it amounted to 33 and 50 per cent. The data presented show that the fact of the contracted pelvis *in itself* does not render the prognosis for the mother any more serious.

42 *Treatment of Surgical Tuberculosis of Bones and Joints. (Des progrès réalisés dans le traitement chirurgical des tuberculoses ostéoarticulaires.) P. Vignard and R. Armand.

42. **Treatment of Surgical Tuberculosis of Bones and Joints.**—Vignard and Armand conclude their long article, which is accompanied by thirty-one skiagraphs of some of the cases reported, with the statement that the natural tendency toward a cure of tuberculosis, especially in the joints in the young, imposes the necessity for prolonged immobilization as the best treatment in such cases. Local injections may be advisable as an adjuvant, especially in residual abscesses after healing over of the bone lesions. They have no action on the latter, as it is impossible for them to reach all parts of the lesion effectually, and the fluid injected has no effect on bone tissue, but in a synovial or abscess pocket they may do good service. Whenever a focus of tuberculous osteitis is accessible, it should be cleared out, and operative treatment is also indicated for a joint lesion if no turn for the better is apparent after five or ten months of immobilization. The operation should be concluded by plugging the cavity left in bone or joint with Mosetig filling. Everything must be done to avoid the necessity for drainage, at least for any length of time. Treatment on these principles is applicable only in cases in which there is no fistula and the kidneys are sound.

44 *Central Nervous System of Children with Inherited Taints. II. (Le système nerveux central d'enfants issus de parents en état morbide.) G. Catola.

44. **Nervous System with Inherited Taints.**—The conception of an inherited predisposition to disease is sustained by the histologic findings in the central nervous system in eight children examined by Catola. The mothers had had tuberculosis, nephritis, pernicious anemia or syphilis, and the nerve tissue in the children showed imperfect or otherwise abnormal structure. The toxins seem to be able to induce hypoplasia or hyperplasia, affording an anatomic basis for the predisposition to disease in such families.

45 *Diffuse Calcification of Connective and Subcutaneous Tissue. (La calcinose généralisée et ses formes anatomiques interstitielle et sous-cutanée.) J. Lhermitte.

45. **Diffuse Calcification of Connective and Subcutaneous Tissue.**—Lhermitte calls attention to an anatomic-clinical syndrome characterized by infiltration with lime of the subcutaneous and connective tissue. This generalized calcinosis, as he calls it, is liable to affect both sexes, but is most frequent between the ages of 8 and 20. None of the specific infections seems to have anything to do with it, unless possibly syphilis. Krause and Trappe noticed marked improvement in their case under mercurial treatment, although there were no signs of syphilis and the Wassermann reaction was negative. Mercurial treatment was even more effectual in Stradiotti's case in which there was a history of untreated syphilis in youth; at the age of 44 a profusion of subcutaneous nodules containing lime subsided under mercurial treatment. The data reported seem to indicate further a close connection between this diffuse calcinosis and scleroderma. In a number of the cases on record there was irregular, pronounced enlargement of the thyroid. In many cases local trauma seemed to be responsible for the first development of the subcutaneous form of the affection. The interstitial or muscle-

combined diuretic action, and by the reduction of blood-pressure by the iodid.

21 *Syphilitic Reinfection. H. FitzGibbon.
22 Sterilization of Certain Degenerates. R. R. Rentoul.
23 Catalogue of the Library of the Royal College of Surgeons of England. V. G. Plarr.

21. **Syphilitic Reinfection.**—The patient whose case is cited by FitzGibbon received syphilitic infection in June or July, 1906, which was followed by the development of complete syphilis early in August that year. He recovered under treatment by intramuscular injection of mercurial cream within twelve months. There was an interval of perfect health from any symptoms from syphilis from April, 1907, until October, 1909, during which time no treatment was undergone. About this time he exposed himself to the risk of infection, which was followed by a characteristic chancre, and the subsequent sequelæ usual in recently acquired syphilis, such as inguinal adenitis, sore throat, etc., which left no doubt of the case being one of reinfection of syphilis which must have taken place in the end of October, 1909, about the time that the patient admitted the exposure to have taken place. The dates of the respective infections were approximately July, 1906, and October, 1909, leaving only an interval of three years and three months between the first infection and the date of the reinfection. The possibility of a second syphilitic infection taking place in a person who has previously contracted syphilis and recovered from it has long since been proved beyond question by the number of cases which have been recorded on reliable authority, but the interval between the first and second infections has always exceeded five years. FitzGibbon regards his case, therefore, as quite exceptional in view of the shortness of the interval which intervened between the first attack of complete syphilis and the second infection.

25 Auricular and Peri-Auricular Dermoids, Fistulas and Tumors of Congenital Origin. J. H. Evans.
26 *A Case of Lymphosarcoma. G. F. Vincent.

26. **Lymphosarcoma.**—Vincent first saw this patient, a boy, aged 9 years, on July 9. His mother noticed on the night previous while giving him his bath that his abdomen was enlarged; that he had vomited once or twice, and that the bowels had acted three times that day. She said that two or three weeks before this some friends had remarked to her that he was not looking well and seemed paler and somewhat thinner, but she had not noticed it herself. When Vincent saw him the temperature was 97 F. and the pulse 100. The stomach appeared to be distended and the costal arches were pushed forward. A considerable amount of free fluid could be detected in the abdomen, and percussion did not give rise to any pain. On July 10, his temperature was 97 F. and pulse 104, and the distention of epigastric and hypogastric regions was more pronounced. He complained of a slight pain occasionally in the right hypochondrium and had some difficulty in micturition. He vomited once and the bowels acted three or four times during the night. He measured over the epigastrium 26 inches, over the umbilicus 23½ inches, and from the xyphoid cartilage to the umbilicus 6½ inches. On July 11, temperature was 97 F. and pulse 108. He did not complain of any pain, but lay in bed reading. An incision was made in the mid-line, when about 4 pints of clear fluid came away. On inserting the finger Vincent felt a large swelling about 3 by 2 inches attached to the anti-mesenteric border of the hepatic flexure, with several swellings the size of a marble dotted over the intestine above and below this; also a swelling the size of a hen's egg surrounding the gall-bladder. Through the incision he pulled out the growth with a portion of the intestine, but in doing so it broke, for it was very brittle, although its walls appeared to be about ½ inch thick. As the gall-bladder and a large part of the intestine were involved, Vincent decided not to proceed further with the operation. He was also suffering considerably from shock, and vomited about half a teacupful of coffee grounds. Vincent replaced the swelling, put in a large drainage tube, and sent him back to bed. He died in thirty-six hours. The necropsy showed the growths on the intestine and gall-bladder mentioned, also large nodules on the lesser curvature of stomach and duodenum.

Annales des Maladies des Org. Génito-urinaires, Paris

October 15, XXVIII, No. 20, pp. 1825-1920

27 *Hydronephrosis with Horseshoe Kidney. (Sur trois nouveaux cas de rein en fer à cheval.) E. Papin and E. Christian.
28 *Cancer of the Prostate. H. Young (Baltimore).

27. **Horseshoe Kidney.**—Papin and Christian report three additional cases, with hydronephrosis in two of them. They have also found nine operative cases on record of hydronephrosis with horseshoe kidney with operative treatment and fifteen cases in which the trouble was first noted at necropsy. Bilateral hydronephrosis in a horseshoe kidney has never been encountered during life. The heminephrectomy in the nine operative cases was successful in all but one; in this the fact that the kidney was of the horseshoe type was not recognized until the attempt had been made to remove the whole kidney mass. Fatal hemorrhage followed from laceration of a large vessel. Albarran did a ureteropyeloneostomy with successful outcome in one of the cases, establishing the possibility and advantages of more conservative measures than the usual heminephrectomy.

29 *Hypersecretion in Fasting Stomach in Relation to Ulcer. W. Oettinger.
30 The Psychic Gastric Secretion in a Gastrostomized Patient. R. Hertz and S. Sterling.

29. **Hypersecretion in Fasting Stomach.**—Oettinger regards pure gastric hypersecretion in the fasting stomach as a sign of disturbance both in the secretory and motor functioning, and says that in at least 72 per cent. of the cases it is the result of an ulcer or ulceration in the stomach. If besides the hypersecretion there is also stagnation of stomach content, the conditions favor autodigestion of the stomach wall. Among seventy-five patients with more or less gastric juice in the fasting stomach, he found fifty-four with "occult" blood in the stool. The hyperacid conditions in the stomach are liable to entail secondarily spasmodic contraction of the pylorus, or gastroptosis or the effect of corsets may aid in the vicious circle. Even in all the twenty-one cases in which the stools were free from blood, there was a history of more or less gastric discomfort, loss of weight, etc., or actual pain.

Archives de Médecine des Enfants, Paris

November, XIII, No. 11, pp. 801-880

31 *Pathology of the Thymus. A. B. Marfan.
32 *Glioma of Base of Brain. A. Hallpré.

31. **Pathology of the Thymus.**—Marfan concludes from his research that some chronic infection or intoxication is generally responsible for simple hyperplasia of the thymus. Syphilis and tuberculosis are the principal factors, and tentative antisyphilitic treatment may prove successful even in the absence of a known history of syphilis. If no benefit is derived from it, general treatment for glandular enlargement should be instituted. Injection of adrenalin, 2 to 4 drops a day of the 1 per thousand solution, seems to have a favorable action on hyperplasia of lymphoid tissue in general, and Marfan suggests its use in case of hypertrophy of the thymus. With threatening symptoms from compression of the air passages, radiotherapy, thymectomy or intubation may be considered. If there is no immediate urgency, radiotherapy might be given a fair trial. Friedländer has reported entire subsidence in an eight weeks' babe of severe respiratory disturbances under twelve Roentgen-ray exposures in thirty days, and Myers has reported similar success in another case, although he had to make forty-seven exposures in the course of three months to realize this result. In emergencies, intubation with a long tube reaching nearly to the bifurcation may

relieve the little patient of all disturbances. Inhalation of oxygen, injections of camphorated oil and artificial respiration may also prove useful. Thymectomy, however, is a relatively simple operation and is indicated in all cases of intense and lasting compression. A number of successful cases are on record.
